The solar cell operates as a (badly) regulated power supply with current limiting. At low load currents, the cell operates nearly as a constant voltage source, but after a specific current (for a given illumination) it operates nearly as a constant current source and deliver approximately that current even into a short circuit.

The largest power from the cell (for a specific illumination) is obtained at the point it switches from constant voltage to constant current mode, in which both the voltage is quite close (within 30 %) of both the maximum voltage (as measured at open circuit) and maximum current (as measured at short circuit).

This maximum power point varies with illumination, but if the switcher always loads the cell at this maximum power point, the largest available energy at a specific time is extracted from the cell independent of illumination.

Even if the losses in the maximum power point tracker is 10-20 %, usually more energy can be obtained than running the module in some non-optimal constant voltage or constant current mode.

The difference for panels perpendicular to the sun on the equator and
the arctic circle in the summer noon is about 10-15 %, due to the
atmospheric absorbtion. The difference between the equator and pole is
about 30 % in the same conditions.

If the panel is tracking the sun, the panel on the pole during the
summer will produce electricity for 24 h each day, while the other
panel on the equator will produce for less than 12 h. On the arctic
circle about 18-20 h each day will give usable electric output.
Exactly at the arctic circle, the midnight sunlight is strongly
attenuated by the atmosphere, so you can look at it even with your
naked eyes or ordinary sunglasses, thus the electric output is also
minimal.

>He might actually have a better chance there during the periods when the sun
>never sets than at, e.g., the equator... solar cells are noticably more
>efficient when they're keep cold, which is typically a lot earier to do in
>the arctic than at the equator!

The silicon cell behaves quite in the same way as a silicon diode
which has a 0,7 V threshold voltage and -2 mV/C temperature constant,
thus the cell output voltage (and hence power) drops with temperature.

However, the cells are heated by solar radiation at nearly at constant
flux on the equator and arctic circle, thus, the main issue is how
well the heat will be removed from the cell to the environment. At the
arctic summer the air temperature can be well over 20 C for longer
periods of time, so this does not help a lot in keeping the cells
cool.

...and the windchill is also reasonably comparable? I didn't realize the arctic could be so 'balmy!' Thanks for the info.

I suppose that if you wanted to push the issue, a heat pipe stuck in the ice going back to a metal layer on the back of the panel would be quite effective in cooling the panel...

Yeah, I see what you mean, sort of like an impedance match, but at DC.
But at the beginning or end of the day, or cloudy day, you can't pull
any more energy out of the cells than there is there. What it looks to

me is that you're adding circuitry to give a better match at the ends of the day or a cloudy day, and in return sacrificing a few percent overall.

My attitude is that rather than try to do this (and in the process lose reliability), it's better to go supersize on the cells, add more area and overall capacity to get you thru the cloudy days, and have a higher capacity overall.

2890. Refresh old capacitors. How to ?

Newsgroup: rec.radio.amateur.homebrew

From: pake@extrafoi.se
Message-ID: <pake-0101040332030001@dhcp-032-102.foi.se>
Source record: 26977

I have a powersupply which have been stored for 15 years.
Now I want to use it. But I think the high volt(500 V) capacitors
need to be refreshed (right word?). (To slowly increase the voltage.)

Questions are for ex.: how fast, how long time at each level.
Cant find any info on the net or in the handbook.
Is there any info on the net ? Or here ?

It's a good idea to choose an IF that is well away from any strong signals.
If you are making your own ladder filter you also need to choose a frequency
for which cheap crystals are readily available.

Plug it in to a Variac and bring the voltage up very slowly. Do it over several hours. Better safe than sorry.

First decide if it's going be to single or double conversion. Easiest woulb
be single with 455 KHz, readily available IF cans, filters and xtals. If
you go double conversion you need to decide if you going to a relatively
high IF such as 40 or 60 MHz but for starters 10.7 mhZwould be good as parts
are easier to get. Read the ARRL handbook.
Good luck

Use a Variac if you have one or improvise. I have had excellent luck going up in 10 volt steps on the AC side going from zero to 120VAC with an hour or 2 at each level. In additIon I let the unit cool for about the same time between voltage increases. After each level feel the capacitor and see if it's getting warm as this usually means it's done for but sometimes smaller steps in voltage increase and longer cooling intervals may increase your luck, the electolyte runs out of luck and becomes too dry to reform! If the unit has tube rectifiers they won't start to conduct till you reach about 60% so you'll not have as nice a transistion as you would with solid state. Try it as yoiu've nothing to lose except some time. Units that have no signs of leakage have reformed and in many cases worked well for years but the odd will fail at the least desireable time.

I have seen elegant ckts where a simple switcher was used, regulating
the *input* voltage coming from the solar cell, keeping it in max
efficiency mode at all loads. This obviously only works with flexible
loads such as slow chargers or such.

Source record: 26984

You have a number of constraints here. Deciding to cover all the HF bands makes it particularly messy. You might consider building a few single banders to get a feel for the problem space.

As Leon said, you want to choose an IF that is well away from any strong signals.

However, you would also like the IF to be well away from both the received signal and the VFO. This helps with image rejection. This is the reason many commercial receivers have a first IF up around 60 MHz. In amateur homebrew practice, you often try to place the IF roughly midway between the received signal and the VFO. If you want to cover all the bands this isn't possible.

As Hank mentioned, selecting a "common" IF means that you can get crystal filters, transformers and the like. However, most of the stuff for common IF frequencies is intended for broadcast use, and is too wide to be useful for amateur practice, so be sure you know you can get what you want. 455 is nice because you can get nice Collins filters, but this almost forces you to double or triple conversion. A low IF makes it easier to build sharp filters. As Leon pointed out, you want to be able to get crystals for your selected IF very cheaply, assuming you will build the filter. You will want to select the best handful from a big bunch. Should you run across a deal on 100 5 MHz crystals then maybe you should pick 5 MHz.

I disagree with Hank on the 10.7 choice. 10.7 MHz parts suitable for amateur HF service are virtually impossible to get, and you probably have a dozen 10.7 MHz generating devices in your house. However, if you are building an FM Broadcast receiver 10.7 MHz parts are widely available. 455 is nice because sharp filters are available, but that is really only feasible in a double or triple conversion setup. There is no way you are going to eliminate images with a single conversion 455 KHz IF for the higher frequencies.

Finally, if you intend to use an analog VFO (which I recommend against) you want to pick a frequency that allows for a low frequency VFO. Stabilizing a VFO is a major pain, and it gets worse as you go up in frequency. You might choose to build a stable VFO for, say, the 3 MHz range, then mix it with crystal oscillators for each band. You do end up with a real challenge keeping the images under control, however. And on 10 meters you would need to have several bands because it's tough to get an oscillator to spread over a large range relative to it's frequency and keep it stable.

You can see this gets to be a huge math problem, constrained by what you can get in the way of filters or crystals to build filters. Your job is simplified somewhat by choosing a DDS approach rather than an analog VFO,

but you still need to sort out how to avoid images in a large number of VFO/IF/received frequency combinations.

Double or triple conversion simplifies this problem, but makes the whole rig a lot more complex. A high first IF solves a lot of problems, but it pretty much forces you to a DDS. A 60 MHz IF gives you a 56 (or 64) MHz VFO for 75 meters - there is no way you are going to build a 56 MHz analog oscillator that is sufficiently stable.

I have to ask why? Building a rig to cover all the bands is a nice technical challenge, but few folks work all, or even most, of the bands. Most people find a few that suits their operating preferences and largely stick to them. Also, you shouldn't imagine that building something will save you any money. You simply don't have the buying power of an Icom or Kenwood. On the other hand, there is nothing quite like operating your own rig, that you designed! But you can get that thrill a lot easier with a single band choice.

Yes to all the OP, but you also need to pay attention to spurious responses caused by mixing harmonics of the LO with harmonics of the RF. The '76 ARRL handbook has a nice nomograph for this; I devised one for my own use but it would take a 5000 word article to explain it.

Pete,

I have my Dad's grinding stuff, but don't do it. One thing to keep in
mind, and I don't know the details, but remember that the crystal activity
is effected by the edges. Grinding the edges is one of the more esoteric
aspects.

Wish I could remember where, but there was something within the last 6 mo
where it talked about monitoring the CURRENT. I would think that HOT caps
are a BAD thing and should be avoided. My guess is that t15 years isn't
long, but better safe...

I agree with Bill, for the cost involved and the impending failure just
replace them. The power supply will be good for another 15 years and be
trustworthy. If one of the old caps fails it could take out the rectifiers
and chokes, not to mention the mess.......Eddie

Hi Harold,

Nice of John to make that offer!

As for background and theory, I'll make copies of an artcile or two to send you, about the discovery of the effect and the optimization of diode structure to enhance it. I suppose that the effect you're seeing with the Schottkys is almost entirely capacitive stored charge, and that won't "sweep out" of the diode with the sharp step you get with a step-recovery diode. The articles I'll send have info about efficiency, which can be surprisingly high considering the high order of multiplication.

Cheers,
Tom

Actually, considering the date of the magazine, they aren't talking
about shifting commercial crystals.

They must be talking about taking quartz, and making crystals. On
the same level as making your own capacitors. I gather it might
have been common back then. Does the date coincide with requirements
of "crystal like" stability? I can't remember when such rules came into
effect, but I can imagine it would have set off homebrewing of crystals.
For that matter, there may not have been that much choice; I have no
idea what the state of commercial crystal manufacturers were back
then. ANd considering it was the thirties, likely many hams had
no money to buy commercial crystals, but they could scrounge.

It was WWII that offered up all those surplus crystals in FT-243 holders.
If you were lucky, some would fall where you needed them. A bit less
luck, and you'd at least find some close enough to your needs that you
could grind them a bit and move them onto your frequency. With no luck,
you'd have to buy crystals.

One could reference the other thread about selecting a receiver's IF
frequency. Often, such selection resolved to what was available. If
you could buy a filter, you'd use that frequency. Likewise when hams
started making crystal lattice filters after WWII, they used frequencies
which were available (which luckily overlapped the common 455KHz IF).
Even today, the choice of frequency for a homemade crystal ladder filter
often depends on what crystals are available cheap. Not the only criteria,
but one of the criterias.

The argument usually goes that getting, say, 10-20% more power from a better charge controller (one of these so-called 'maximum power point controllers') can be cheaper (in additional expenditures) than getting 10-20% larger panels. It's sometimes difficult to show, though, particularly on small systems -- but MPPT controllers have been getting cheaper for awhile, now, and I expect that eventually all but the cheapest/smallest will have this functionality.

Here are postings I made on this topic on this group on August 1, 2001 and April 22, 1999. I'm sure you can find a lot of other relevant postings with a google groups search.

You apply a variable DC voltage through a current limiting resistor. Adjust the voltage so that the capacitor draws a few mA of current. (What you want to avoid is excessive heating of the capacitor.) As the dielectric layer thickens, the current will slowly drop. When it does, increase the voltage again to get the current back up to a few mA. Continue this until you've applied the full rated voltage and the current at that voltage has dropped to a very low level. Or you can use a fixed voltage source equal to the rated capacitor voltage, and vary the resistance to maintain the desired current.

One point that hasn't been mentioned here is that the voltage-handling ability of electrolytic capacitors declines if they're stored for long periods without use. So a capacitor might be bad after long storage, but can be brought back to life.

The insulator is a coating which is plated onto one of the electrodes by an electroplating process. This process naturally occurs due to the applied voltage when the capacitor is in use. When stored for long periods, the coating deteriorates and must be re-formed to restore the capacitor to its original voltage rating. (An associated problem is that when in use, the dielectric coating will, over a long period, naturally degrade to match the applied voltage. So if changes are made in the circuit which raise the capacitor voltage, say by replacing an old rectifier tube, the capacitor can leak or explode due to the suddenly increased leakage current.)

An electrolytic capacitor is re-formed by applying a voltage through a current-limiting resistor. The voltage is slowly increased until the leakage current reaches some specified value, then left at that level until the leakage drops to a low value as the dielectric layer forms. Then the voltage is increased until the leakage current again increases to the limit and left at that value for forming, and so forth, until the leakage is adequately low at the rated voltage.

There are various rules of thumb for how large a leakage current can be tolerated during re-forming. One reference I have for modern capacitors gives 5 mA for small PC-board-mount capacitors, and 10 mA for large computer grade capacitors. It seems to me the important

thing is to limit the temperature rise, so the tolerable current would
really be a function of capacitor size and the voltage across it. A
quick look at the _ARRL Handbook_ index didn't reveal anything about
this topic, but I know it was in the Handbook many years ago. The
folks on the .boatanchors newsgroup should be able to provide a lot
more practical information on the topic for those who are interested.

In my limited experience, you have to be a little careful using a switching, or even a series pass, regulator with a solar panel. Most are designed to regulate voltage coming from a relatively stiff source, and some become unstable when hooked to a high impedance source like a solar panel. This can often be overcome by putting a big capacitor across the panel, and it can of course be overcome by designing the regulator to function properly with the high impedance source in the first place. And quite a few regulators work just fine without modification. But it's something to keep in mind when using a regulator designed for more conventional applications.

That is exactly the point, Joel. Upsizing 20% is several times more expensive compared to providing an intelligent switcher to match to the illumination or to adapt a panel voltage that isn't matching the storage devices. That situation won't change unless there is a tremendous breakthrough in technology or serious new government subsidies.

As to reliability, a switcher that is designed correctly and conservatively should easily outlasts the cells. Even for small installations it is easy, especially in view of the large variety of micro controllers that retail for a few Dollars. One of these plus a few discretes and an inductor can do the trick.

Regards, Joerg.

Tom,

I'd appreciate a copy of that stuff. The history of the Boff Diode is
kinda neat.

I have some papers (hardcopy... faxable) on the Grehkov-effect drift
step-recovery diode; we use it to make 2400-volt, 3 ns wide pulses at
500 KHz, as long as the cold water keeps flowing.

This was actually just before then, when crystal stability was expected
but not (I believe) required. The '33 handbook "starter transmitter"
was just a TNT oscillator connected to an antenna.

No, the good _really_ 'ol days of taking a chunk of quartz, whacking pieces off of it with a mud saw, hand lapping the saw marks off and mounting it in a home-made holder. That namby-pamby FT-243 wasn't invented until just before WW-II.

The same magazine has an article about the blind ham who built his own equipment. Soldering by feel. There were giants in those days...

Just for efficiency reasons, I think you would want ot have enough
capacitance across the regulator input that the cell resistance drops
voltage only with respect ot the average output current, not the
switcher peak value. This can be a pretty big factor in the overall
efficiency. Using a switcher that has little ripple current on its
input (two phase boost, for instance) makes this much easier.

What's a sensible target for the multiplication factor using diodes
from say a 4Mhz source? I'd be nice to go straight to say 20X on
account of the large physical size of the filters at lower HF., not to
mention the savings on intermediate stages.

actually, it is a lot easier to simply etch or grind away some of the xtal, then check it with a grid dip oscillator for sharp dip, no need to remount and test ;-) An old Hints and Kinks IIRC. This could be really handy if you wanted to make a xtal filter and needed to really match and control the xtal freq offsets (what, 3.5179 Mhz xtals from TV color burst sources?) ;-)

and how about drilling a small hold in the holder so you could tread a small bolt to put pressure on the xtal holder plates, shifting the xtal freq. around like a xtal controlled VFO - but only a handful of khz ;-) Still, very solid (pun intended) freq. source that can be varied around enough to avoid QRM at minimal cost and effort for QRPers and so on? ;-)

Wasn't there a recent historical article in QST on the role of the quartz xtal industry in WWII, how they figured out overtone osc. issues and so on?

Given that some sources ask $12 and up for scanner and ham crystals, these costs add up rather fast if you need to replace a bunch of xtals in a scanner. So the search for alternatives seems quite worthwhile ;-)

>

That's not the point. Because a switcher tends to draw a constant power from a load it's input impedance has a negative resistive component. If you match this with a source that has a too-high impedance it'll be _unstable_; a big capacitor would just slow it down in this case.

Presumably what you need is a controller that detects when the supply voltage gets down to some threshold, then regulates the supply-side current rather than the load-side voltage.

Come to think of it that'd be a fun thing to design...

The trick isn't the edges but keeping the two surfaces parallel and
flat. The procedure is to grind a little
and check the activity. If it is down try to grind the center or edges
and check again. If it gets better
then go back to to grinding and trying to keep it flat.

Anyway that is the method I used.

Very few switchers draw an instantaneously constant power from the
unregulated source. Almost all can draw an average constant power
(over the switching period). The difference means a lot when you
consider what the variations do to the total losses in the solar
cells. You missed my point, completely.

An 8 MHz filter doesn't have to be physically large Paul, and efficiency drops pretty fast (Think like a rock) as the multiplication factor goes up. Have you ever actually defined what it is you're trying to do? Some control thing in your 70 MHz band? Or real power for some application? Hard to hit a moving target. Or is that the idea?

The last time I looked at one of these, what I found wasn't a latching relay in the usual sense. It's a solenoid which drives a rotating two-position switching thingie. There isn't a separate "set" and "reset" coil.

But they already figured out the solution, thirty years ago, and
it did not require going to the quarry for quartz and digging out
old QSTs. The need for a lot of crystals luckily coincided with
digital ICs, so before most people could get around to paying for
all the crystals to fill out a mult-channel unit, synthesizers came
along so you only needed one crystal. About as soon as it could be
done practically, hams built them and wrote up articles in the ham
magazines.

Anyone who decides to make their own crystals today, other than
for the sake of doing so (and I admit it would be an interesting
thing to try), will likely find they can't go for the subminiature
look, and probably will find that putting effort into building
a synthesizer still makes sense if you need more than a few
crystals.

Absolutely: You should only make your own crystals for the same reasons
you'd knap your own stone tools -- to understand how it was done back in
the day, and to have some thing to show off to friends. You could get
crystals much faster by cleaning toilets at McDonald's and buying them
at $12 a pop than you could making them from scratch.

This type of relay would work depending on the coil voltage. However
I would guess that voltage is also 120 volt.

What I am trying to do is have the ability to switch 4-5 different
lights (150-1000 watt) from several locations within the same building
without all the hassle of 2 and 3-way switches.

My plan is to have a relay bank that these lights would source from
(total wire run of 60-75 feet) then have small low voltage/current
pushbutton switches activate the relays. 4-5 small pushbuttons could
control any light in the building from that location.

I have thought about X10 but have also read more bad than good about
the wierd things they do or don't do.

While there certainly are going to be stability issues, using a
switcher with say 50 % duty cycle will draw 0 A half of the time (i.e.
the PV cell is operating in the constant voltage mode) and 2 Iave the
other half of the time (i.e. the cell would operate in the constant
current mode) and never operate at the maximum power point (here
assumed to be at Iave).

Sufficient parallel capacitances and/or series inductances or some
push-pull arrangement will keep the current constantly at Iave and
thus at the maximum power point.

All latching relays have a dual coil setup, with a mechanical latching
arrangement on the armature.

If you want just one coil, you need a simple flip/flop driving a
transistor whose collector load is the relay coil. Lots of example
circuits in the Handbook of Electronic Circuits Vols 1-7.

Anybody got any real data on this stuff.
I set out to build a constant power solar battery charger.
I was gonna just put a PIC to measure the voltage/current and
ratchet the switcher duty cycle up and down around peak power.

Went out in the yard at noon and plotted some curves. Yep,
there's a pronounced power peak right around 14V.
At lower intensities, the shape of the curve is the same, but
it moves sideways. Ok, my pulse width strategy should track that.
Cool.
Then I turned the panel ever so slightly away from the sun.
I was amazed at how dramatically things changed with just
a small angle. Looks like I'd gain WAY more watt-hours/day
by tracking the sun
than by anything else I could think of.

> mention the savings on intermediate stages.

Well, somewhat counter to what Harold wrote, the old HP Journal
article I've dredged out to copy says a step recovery diode can do 20X
at 30% efficiency. But that's guys who really understood what they
were doing! (Just coincidentally, the one table they have is for
20X!)

He's right...the filters don't have to be huge. But I'd think of them
as large compared with a SOT-23. The tradeoff is that if you do it
all in one step, you have to have a filter sharp enough to take the
19x and 21x down to your desired level, whatever that is. But with a
5x and a 4x, you can use a couple filters with wider percentage
bandwidths, since for the 5x you'll be using a square-wave input which
has practically no 4th and 6th anyway, and the 3rd and 7th are a big
percentage removed from the 5th...and the 4x can similarly avoid the
3rd and 5th if you do it right.

But again, a PLL can be very small indeed. And I never did see an
answer to the question about does it really need to be locked to your
low freq, or can it be a separate xtal at 70MHz or whatever?

Cheers,
Tom

>thanks

First catch your rabbit (i.e. a filter).

That is how a certain rabbit pie recipe starts and the same is
often true of radio projects. Joe Ham comes back from the yard sale
with a pair of tubes or a large transformer and then builds a linear
around what he has found. So go look for a good SSB/AM filter and
design the rest to suite.

A good compromise is 9MHz, as you can probably get away with
single conversion. Some of the tighter spec filters are at 455kHz
however but then you will have to go the dual-conversion route. Both
work, it is simply 'horses for courses'. If you want to put a roofing
filter up front, you could try a narrow 10.7MHz from an old mobile
radio but you will still need a narrow one after it.

> Anybody got any real data on this stuff.

There's no shortage of information about this. Useful keywords are "insolation" and "solar insolation" (the word "solar" is slightly redundant but it's commonly included). In summer, you can expect a maximum of 1 kWatt per square metre to reach the surface of the earth. The units most commonly used are kW-Hour per square metre per day - I'll call them Units here.

Insolation tables for the USA can be seen at:
http://www.suntrekenergy.com/sunhours.htm
These figures are somewhat suspect - the difference between "high" and "low" seems too small (a maximum of 6 Units is rather low), especially when compared with the following, which contains some good maps:

http://www.wattsun.com/resources/insolation_maps/map_index.html

On this page, click on Flat Plate Collector, Single Axis Tracker and Double Axis Tracker. The latter can produce up to 14 Units in summer. The improvement when tracking the sun's angle is very large. It pays to live in California.

I have seen a similar table somewhere for the UK, showing that 5 Units is the best that can be expected, and maybe less than 1 Unit in winter.

Bear in mind that the efficiency of Solar Cells is less than 20% in the very latest state-of-the-art devices, typically 10%, and maybe as low as 5% in reject/hobbyist cells. Generating hot water directly from flat solar collectors is probably more efficient, and certainly cheaper, but not much use if it's electricity you want.

If, on a bad day, the cell voltage is less than the battery voltage, you can still charge the battery. Look at:

http://www.elecdesign.com/Articles/ArticleID/6262/6262.html#
This article appeared in Electronic Design, Sept 14 1998.

It describes a circuit for a Maximum-power-point-tracking solar battery charger. The principle is simple: the duty-ratio of a switch-mode power supply is continuously modulated at about 50Hz. The change in output on each cycle

is used to determine whether a higher or lower duty-ratio would increase the output power. A phase-sensitive detector and feedback loop determines whether to increase or decrease the average duty-ratio. It settles at the point of maximum power.

As the article points out, it works for other energy sources such as water-wheels and other devices where the shape of the "energy curve" is not precisely known.

When used as a battery charger the voltage of the battery is fairly constant, so "maximum power" means "maximum current". At the solar cell end, we are working at maximum power, although the voltage may vary. The "maximum power transfer" condition is when 50% of the power goes to the load, and 50% is dissipated in the cell. I don't know if this is precisely true in a solar cell, but it certainly implies considerable power dissipation in the cell, which may shorten its life. On the other hand, a cell of 1 square metre will have 1000 watts of solar power falling on it, and may generate 100 watts of electrical power, of which we may get 50 watts into our battery. The 50 watts dissipated in the cell is much less than the 1000 watts from the sun - so maybe it doesn't matter.

This is miss leading.
While there are places, nearer to the equator, that
can have 1KW/m^2 at noon this is not the norm.

The rule of thumb is 1KW/m^2 normal to the sun
not flat on the ground.
Or about 100W/ft^2.
This is a tilted surface directly facing the sun.

Yep. It doesn't take much of an angle from perpendicular for a
silicon cell to act as a pretty fair mirror.

Wow, I have lots of 15 y.o.+ electrolytics that are still going strong.

I didn't have a variac, so here's what I did to rejuvenate a SB-200 I restored a while back:

I made a fixture of a standard light bulb socket.

This socket was wired in series with the amplifier power cord.

Starting out with a 10 watt light bulb, I plugged it in, and turned it on. I left it running in this setup for an hour.

Next I replaced the 10 watt bulb with a 25 watt bulb. Repeat the burn in process.

I worked my way up the wattage scale until I reached 100 watts. At that point I put the tubes back in, turned it on and it worked just fine.

Last nite (Tue, 9pm) I watched a prog on PBS that was about getting
people to use more renewable resources, hosted by Cameron Diaz (hot
blonde movie star), who drives a Prius. They talked about getting every
home to have a solar panel, and selling power back to the utility co.
She also said that if everyone in the U.S. drove a hybrid vehicle, we
could completely eliminate oil shipments from the middle east. Well,
I'd go out and buy a Prius, but one of the guys at work has had his new
Prius since xmas and it took him 4 months or so to get it after
submitting a $500 earnest check to several dealerships to get on their
waiting list. They say they're trying to make more of them, but I think
they really don't want the prices to fall, since they're expensive to
make. In any case I'd like more solar power, but the initial outlay is
not cheap.

Yeah, moving target's good. Keep the discussion generalised and it
might help others as well. I'm not sure where the 70Mhz figure comes
from, but it's a good enough guess by whoever made it. However, the
final desired frequency in my particular case is in the region of
40Mhz which will be achieved by mixing down with the output from
another oscillator and filtering.

Randy,

The relays that I described in my other post came out of a house that did exactly what you describe. The relays were made for just that purpose. Most of the light circuits were switched with these relays and low voltage wires were run to various places to control them. They had 2 push buttons for each relay. One for on and one for off.

Thinking about it, that is better than using only one button. With one button you are never sure if you are turning the circuit on or off. Especially if the light happens to be remote from where you are.

Each switch location had a 3 wire cable run to it. The 24 vac transformer was mounted where all the relays were mounted. Next to the breaker panel. I think there were around 40 relays that I got out of there. It was a big house.

With this setup you can control a circuit from as many places as you want to without getting into complicated wiring.

Not trying to sell you relays, just telling how it was done.

While I'm all for using more renewable resources, and especially ones that are environmentally friendly, it doesn't make sense to cause yourself financial pain doing so. It makes sense to buy the must fuel efficient vehicle that fits your needs but not to overspend simply because it's a little better on the gas mileage.

That said, there are many things you can do that are quite affordable. First, you could conserve energy. Replace old appliances with more efficient ones, insulate your home better, weather-strip, storm windows, compact fluorescent lights, activate the power saving on your computer, use xeriscaping and all that lot. If you are a typical homeowners then conservation alone could be as effective as putting up a $30,000 solar panel setup.

Then you could buy more affordable renewable energy equipment such as solar water heaters, air heaters, ovens, stoves and the like. You could also change your diet to include less animal products. Raising animals to produce food takes many times more resources (which often means energy) as plants alone require.

There are also many alternatives to a Prius. One option would be to get a diesel powered car and use biodiesel or get it converted to run on straight vegetable oil. Another option is to buy an electric car. Currently the only ones available are "city cars" which turn out to be glorified golf carts but they are suitable for very local driving and can sometimes work as a second car. Some folks have even had great success with bicycles of various flavors. If you simply must have a hybrid vehicle then a much wider selection of them should be available within the next 10 to 15 years.

Bingo, that is my opinion also.

> Yep. It doesn't take much of an angle from perpendicular
> for a silicon cell to act as a pretty fair mirror.

Basically the power output will be:
COS(angle) * Watts
Watts is the output of the panel when aimed normal to the sun.
Angle is how far off of normal the panel is oriented.
0deg = 100%
8deg = 99%
11deg = 98%
18deg = 95%
30deg = 87%
45deg = 70%

However somewhere around 45deg or a bit more the cover glass
begins to act more like a mirror and the panel outputs much
less than allowed by the COS rule. Some panels can improve
on this with anti reflective coatings. These coatings may
not have a long lifetime though.

Now if you use a solar tracker the panel can be oriented
close to the ideal angle throughout the day. This significantly
improves the energy captured per day.

As an example:
At summer solstice where I live, 45deg latitude, the sun
subtends an angle of 270deg. That's an 18 hour day.

6 hours of the day the sun is actually behind a fixed panel.

Another 6 hours or so the sun is at an angle where the output
is low or negligible.

Only during 6 hours or so will the panel output significant
power. And the average power output is less than optimal.

A solar tracker in my location can theoretically harvest
3 times as much energy as a fixed panel.
OK, practically, due to weather and thick atmosphere the
output is 2.4 times according to the NREL data.

Other times of the year the improvement is not as much.
But even at winter solstice the improvement in output
is 1.4 times the fixed panel.

Solar trackers, at least the electronic bits, are really
low in cost, $35 for mine. The total cost including the
tracking mount is much cheaper than the cost of adding more
PV panels for the same outputs.

There are places where the tracking costs aren't cost effective.
The california sea coast and in maybe 50 miles or so is an
example. The local weather has lots of fogs which lower the
solar insolation except when the sun is high in the sky.

One must study the NREL data to see how cost effective
your location may be.

Nope, sorry. I don't have access to the binaries groups, and in
addition, it's copyrighted material. I'm willing to make a very
limited number of copies, but not to post it.

The articles I have are old HP Journal articles, available in
"Inventions of Opportunity," copyright Hewlett-Packard Company, 1983,
ISBN 0-9612030-0-5. You may be able to find that in your library.
The articles in that book were chosen to represent seminal ideas and
products that opened new horizons, so the SRD items are as much for
historical interest as for technical info.

You'll find a little more modern technical info in HP AN-1054,
available at http://rf.rfglobalnet.com/library/ApplicationNotes/files/1/An1054.pdf.

Cheers,
Tom

This coming Sunday....

+++ Now even more Buyers Parking !!!
Thanks to TKT we have use of their new parking lot
across Albany St from the SWAPFEST !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday April 18th 2004
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776

Nice idea, although in her particular case I'd be willing to bet that she could be driving a Hummer and it'd be a small drop in the amount of energy she uses for transportation! (Due to all those jet rides...)

> They talked about getting every
> home to have a solar panel, and selling power back to the utility co.

I'm all for net metering (power company has to pay you the same for a kilowatt-hour as what you would have had to pay to buy it from them), and happily it is becoming more common in the U.S. Panels and controllers are continuing to get cheaper as well. Additional government support could really help improve how many people would seriously consider sticking photovolataic panels on their roofs -- I imagine right now it's well under 1% of the population.

> She also said that if everyone in the U.S. drove a hybrid vehicle, we
> could completely eliminate oil shipments from the middle east.

We could do that as-is... there's plenty of oil in Alaska, after all, we've just made the choice that protecting the environment up there is more important right now than not importing oil from the middle east. (This is a very involved topic -- if anything, the choice of where we get our oil from is far more political than technical in nature anyway.)

> That said, there are many things you can do that are quite affordable.

Yes, such as building better-insulated dwellings. I find it appaling that here in Oregon where I live, the building codes don't require some apartment complexes to have any insulation whatsoever in their attics. These places additionally inevitably end up with electric heat, so the end result is that a small savings to the guy who builds the apartment complex ends up being a huge cost in additional energy to the renter as well as the corresponding impact on the environment.

> There are also many alternatives to a Prius.

Although I understand the reasoning behind it, it's quite ironic how many people out there who live within an arguably quite reasonable bikable distance to their place of employment instead drive to work and then drive to a fitness club afterwards to work out. :-) Although I am all for people using their cars as much as they want so long as fuel taxes or whatever more or less make up for the impact to the environment, but unfortunately it's hard to translate that impact into monetary terms.

It's not a "little" better, it more than double - 50+ MPG compared to 25!

[snip]
> You could

Right, but it's **you** (see above) that said to not cause yourself
financial pain. Well, I _try_ to do my part to eat little or no beef,
instead eat chicken. But I _have_ to pay a premium to do so, even tho
it's cheaper to bring chicken to the table, just because of supply and
demand issue. People consume less beef so the price drops below
chicken, not because it's cheaper. So I and everyone else hasto pay
extra for, helping save resources. Just what you said _didn't_make_ sense_.

Again, you're asking for people to make a financial sacrifice when buying an electric vehicle. The last I checked, it cost $46,000 to purchase a RAV4 EV, with a good chunk of that going to the installation of an electric charger in the owner's garage. According to you, that financial pain 'doesn't make sense'.

> If you simply
> must have a hybrid vehicle then a much wider selection of them should
> be available within the next 10 to 15 years.

In the next 10 to 15 years, the situation may be much, much worse. The big worry in the near term seems to be China, with 1/5th of the world's population, which may have a growing economy that will gobble up an ever growing part of the world's non-renewable energy resources. In 10-15 years, it may be too late! The price of fuel in europe is already over $5 a gallon, and we Americans are currently bitching about having to pay over $2! Well, wait until it goes up to $3, or more! All those SUV owners in the U.S. will be taking tbe bus to work. Time will tell!

Surprisingly enough some SUV owners actually need the SUV at the time of purchase, I personally drove through snow 70cm deep on a regular basis prior to my recent job change. Just because the people in southern California don't need it doesn't mean no one does.

Hello and thanks for taking the time to read this.

I am seeking a piece of software I once used that calculates LCF in various combinations This software was DOS and is freeware.

For the life of me I cannot remember that name of it.

Does anyone know of freeware that does this, and where it may be found?

Thanks es 73 de WA2AFD

2963. Need help to meas noise v of a JFET

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-14 21:33:14 UTC
From: sdeyoreo@hotmail.com
Message-ID: <7gbr70pn5l5o55a5uca614oa376v23aju3@4ax.com>
Source record: 26849

I need to measure the "equivalent noise voltage", in units of nV/square root(hz) of a JFETs drain-source at a given Vds & Ids and F=10 hz. How do I do that? What's throwing me is the F=10 Hz. What do I do with that? I thought to take the measurement, I would bias the FET to the required Vds and Ids and measure the voltage across the drain - source with an RMS meter. Then divide that by the sqrt of the bandwidth of the RMS meter. I've Googled, but didn't find anything to straighten me out. Any help?

The definition of "little" can vary. :)
Would you consider 5 MPG a "little" ?

http://www.fueleconomy.gov/feg/bestworst.shtml
Shows the Prius at 60/51 mpg with a couple of VW's in the 38/46 range.
This is only 1.6/1.1 times and not double, especially when considering
highway driving instead of city driving. This means you can purchase
a vehicle with good fuel efficiency without buying a Prius or even
a hybrid.

You could chose to eliminate chicken as well as beef, eggs and dairy.
I'm no expert in either nutrition or food prices but I think you could
quite affordably manage a diet that does not include meat of any kind.
Perhaps you should look at a group such as misc.consumers.frugal-living
and ask for recipes. You could also look up many of the resources on
the web for vegetarians and vegans.

I agree, a RAV4 EV might not make sense on a financial basis. The last I heard they don't make them anymore. Any you do find are collectors items and will be priced accordingly. In fact, it might actually be rather difficult to find a brand new EV, even the golf cart style like the Chrysler GEM, as they keep getting discontinued. That said, a small neighborhood electric vehicle only costs in the neighborhood of $5,000 to $6,000 when they can be found.

There are many worries in the world and it's always too late for some things. Time will certainly tell but there ARE some things that folks can do now if they like and without putting themselves in debt for the rest of their lives.

2966. Re: Refresh old capacitors. How to ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-14 23:09:40 UTC
From: Allan Butler <ka0ies@hotmail.com>
Message-ID: <Uwjfc.40276$rg5.68332@attbi_s52>
Source record: 26852

I worked at a broadcast radio station that had been in service about twenty years and we were starting to get random failures in the capacitors in timing circuits. These capacitors had been in service for the full time that the station was on the air and the station was a 24/7 operation.

I would vote on replacing the capacitors and still doing the gradual increase of the input voltage. Normally it doesn't really help to do that but there have been rare cases where a new capacitor surprises the new owner with a loud bang.

T'aint fair Tom! That URL is FB and I have it added to my library, but when I tried to trick it and deleted the AN-1054.PDF, and retyped AN-983.PDF, it can't find that one. Suppose I could write a little program to check AN-1 and step 1 then find out what if anything I had. Is there some secret code as to how this all works?

Regards

W4ZCB

(I suppoe it wouldn't be a secret anymore if you told me.)

The May 2004 Issue of World Radio just arrived...

I don't get this one very often, must be the annual free issue.

Very neat magazette!

Good article on portable dipoles made from mobile whips,
an article on YL's at Dayton (hahah) and son of a gun....

Flying Pig Dan Shepherd has an article about identifying
all those little capacitors!! N8IE is such a authoring
machine! (See Page 44)

Richard Fisher KI6SN has a great QRP article and what
looks like a really cool ugly built 40m or 30m transmitter.
It's a whopping 1 watt out, you pick the crystal!

Kurt Sterba has your basic "What is an Antenna"
article. Good reading!

Well that's it.

A lot of automobile headlight relays switch states with a pulse to a
single coil. They're 12V, too.

I once read that it takes more energy to make, deliver, install a solar
panel than the total energy you get out of it over it's 20 year
lifetime. If that's true, (small scale PV) solar makes little sense
from an environmental standpoint.

Hello to the group,

I just found this forum and hopefully, I can learn some more about homebrewing stuff. I have been a hobbyist in electronics for a little over a year now and recently received my element 2 tech license. Last year I built an infrared transmitter and receiver pair to trigger my camera remotely (about a 50 foot range). Since then, I have wanted to do the same thing with RF. I have a tek465b oscilloscope and a dmm, and have built some of my own test equipment (square wave signal generator, power supply, battery tester) and lots of timer circuits with 555's and cd 4060s. Recently I have been experimenting with audio and ultrasound with opamps. All of my projects are battery operated.

I recently bought the Velleman RX 433 and TX 433 modules to try and remotely control my camera. Each module has a 'data' pin, the receiver also has a linear pin, which I am not sure how to use yet. I have been reading the data sheets and app note on the velleman site and it shows something called a HT12E being used to generate the data on the TX module and a HT12D to use these modules for remote control. I googled for the HT12E and it says it is a LSI encoder and you need the HT12D as the matching decoder (on the receiver). Not being familiar with all the terminology yet, I am wondering why I couldn't just generate a square wave to the data pin of the TX module, and, then, at the receiver, use a divide down counter to make sure enough pulses arrived, and then trigger my relay. Does anyone know if this will work? or would it just be easier (and maybe more reliable) to use the HT encoder and decoder?

I am asking because I am not familiar with the type of waveform or pulse shape that the Holtek generates, and, I am not sure if I just want to try pushing a 555 type square wave thru my TX unit and maybe end up letting the smoke out.

Any suggestions or ideas are appreciated.

TIA,
Joe

It's probably a lot more common to express the noise referred back to
the input, but if it's output noise you want, that's fine too. You'd
want to either use a drain load that's much higher resistance than the
output (drain) resistance of the FET at that bias--or else account for
the shorting effect of the load.

Often the noise is so low you would be served well by amplifying by
100 or 1000 so your "meter" has enough to measure accurately.

If I were doing it, my "meter" would be an FFT-based spectrum
analyzer, which would be able to read the amplitude directly in
V/rtHz; then I'd just divide by the gain, if I'd used an amplifier.
(I have a very low noise amplifier I use for just such measurements,
so the amplifier doesn't contribute a lot to the measurement, but even
then, it may be necessary to subtract out the amplifier's noise
contribution.) If you really need to know it at 10Hz, you probably
should not use a bandwidth much more than a couple of Hz. An
FFT-based analyzer (or possibly other spectrum analyzer, or even a
wave meter/analyzer) makes that fairly easy. Not sure this will help
in your particular situation.

Cheers,
Tom

My understanding is that improvements in the efficiency of the panels has no longer made that true... although of course to some degree it depends on where you end up installing the panels!

An easy way to determine whether or not the statement could be true is to see whether or not the cost of the energy produced by the panel over its life -- using regular market rates -- exceeds its cost. If so, obviously the panel must be producing more energy than was requried to build it, since all the labor and materials the manufacturer put into the panel weren't free!

Well, I just typed a search string about SRDs into Google to find the
AN1054 reference. I don't have any magical ideas about finding ALL of
them on the web, but when I moved out library a few months ago, I made
a point of NOT tossing out the ap notes. There's a chance we have it
at work. Now, can I remember to look? Luckily, I didn't find enough
stamps to mail the other stuff off to you and John yet, so if I can
find it, I can stick that one in too. Best magic I can think of for
it at the moment. There are some other SRD-related ones listed in my
Communications Components catalog from 1993: AN918, AN928, (AN983),
AN984, AN989. It does list HP part numbers for each one. "To order
literature, ... 1-800-537-7715" but that's from a long time ago...

Cheers,
Tom

Nor does it pay for itself in any reasonable time,
if at all, if you are grid connected. (If you need to
spend a huge amount to get connected to the grid,
solar can become very attractive.)

A guy in Florida quoted 48 years pay back time. I ran
the numbers for my home - over 40 years, and I pay 13
cents per kwh. A 2 kW system costs $15000. Assuming
an average of 8 hours per day of 2kW per hour, that
solar system would give me 16 kWh. I pay 16*.13 or
$2.08 for 16 kWh. Works out to 19+ years for payback,

if you don't count on mortgage payments for the system.
Add that in, and the cost of a $15000 system is
much worse - over 30,000 in a 25 year, 7% mortgage.

Hi Joe,
IMHO the linear output of the RX is for testing purposes, you should
let it unused. The encoder/decoder pair is used as a key-and-lock, for
better reliability and security. Your solution using a pulse generator
at the TX side might do for a camera remote control - it can be less
safe than, say, a car alarm. A bandpass filter or a PLL checking the
frequency of the pulses on the receiver output should work even better
than a counter only.
The TX unit has limits for input voltage and frequency. If you do not
exceed them, no damage should take place.

Williams at Linear Technology has written several application notes which discuss the practical measurement of noise. Search on their website for a PDF entitled "Characterization of Noise in Low Dropout Regulators" -- not that you are measuring an LDO, but the techniques should be valid.

Message-ID: <hCwfc.8993$hg1.4575@nwrddc02.gnilink.net>
Source record: 26873

It has been a few years....

The noise density in the JFET has a strong 1/f characteristic. This means it increases by 6 db each time you halve the measurement frequency. For silicon, I recall the corner frequency being in the ~ 100 Hz.range. The unit "nV/root-hertz" is the noise density, not the noise. You need to measure the voltage within a finite bandwidth. From that, you can derive the noise power, then the noise density. When measuring below the corner frequency you have to account for this 1/f slope.

Thermal noise in a 50 ohm system at room temperature is about 0.9 nV/root-hertz. In a 1000 ohm system it is about 4 nV/root-hertz. This will set the lower measurement limit, you test equipment will probably limit you to worse than this. Using adequate measurement bandwidth and correct circuit resistance (within the confines of the JFET parameter range) will provide sufficient noise voltage to actually measure, but it will take some gain (via a very low noise measurement amplifier) to produce something you can hook to a measuring device.

There are lots of subtle way to make noise measurement errors. I recommend that you use the test setup that is specified by the manufacturer to make the measurement, otherwise your results will likely not correlate with their numbers.

M-Pulse is good guys; we use some of their faster parts, and they are
very helpful. But they apparently don't stock anything, and wire-bond
- even samples - to order. So if you only want a few pieces for
yourself, and don't intend to place a production order, you'll have to
lie to them to get samples.

Metelics is similar; they seem to make the fastest SRD (35 ps) you can
buy on the open market. Not as friendly as M-Pulse, though.

Thanks alot for your help, I really appreciate it. Would you look at this FFT analyzer: http://www.srsys.com/products/SR760770.htm and do you think it will "see" 20nV/sqrt(hz) or will I need an amp? What do you use as a low noise amp? This FFT analyzer has noise floor of 10 nV/sqrt(hz) and dynamic range of 90 db at -60 dbV full scale range. Again. I really appriciate any help.

You can also roll your own, particularly if you're doing code-only. I
think the current ARRL handbook has info on home brewing crystal filters.

And what does a 2 kWh system cost 15,000 mean ? is that what you paid or just some made up numbers like your 16kWr per day which is pure fiction ..

I built my 6 kWh system for 17K ...

www.solar-guppy.com , you can see my invoices and the system installed in the photo gallery. Also under real-time status you can see the energy being delivered ... , anyone can buy the parts today for a similar amount , check out the solar deals sections for links http://www.solar-guppy.com/forum/viewforum.php?f=12 as examples.

My average per day is about 24kWr/day so far (3 months) , my electrical rate is now 12 cents kWr (they have raised the rates about 2 cents kWh in the least year , more increases to come for sure)

24 * .12 = 2.88 .. 17,000 / 2.88 = 5902 (days) = 16.17 years My , Real system , My real rates NO REBATES ...

Do the same thing in California , where 65 % of the cost is covered (50% materials , 15% state-tax rebate) and the payback is reduced to 17k * .45 = 7650 ... 7650 / 2.88 2656 (days) = 7.27 years .. its actually much better in CA than this since the rates can be TOU (time of use) , the typical CA rates are .15 - .25 kWhr ... putting the payback at 3.49 years at 25 cents kWh (a typical afternoon TOU rate) ....

Surprisingly enough, many of those people who bought a big Ford
Expedition or GM Yukon could have got by with a lot smaller, and hence a
lot more economical SUV. ALso, there are vans, too, with a much better
gas mileage. Surprisingly enough, it's not about whether or not it's a
SUV or a truck or whatever, it's whether or not it's a gas guzzler.

The current issue of home power magazine directly answers this ...
www.home-power.com

It is a myth (your understanding) , panels recoup there cost in about 2-3 years and will last much longer than 25 years. The 25 years , is the manufactures warranty for 80% power generation .... The panels will last until they suffer physically damage, the silicon will deliver power well past our or our children's life times ...

Sounds important, Bill, but my words may have been misunderstood. By
edges I meant the end surfaces...as in ; stand the blank up on one edge -

vertically - there are four of 'em. I don't remember if he said that the ends must be made to have a 90 degree angle with the faces or what. I just remember that he said that you grind these sides for best / better activity.

I was not referring to the outer reaches of the two large faces as in; is the face flat or curved in some way.

Bill, I have to agree with you. This is a NON-ISSUE.

Having had some experience in electron-pushing, mostly hands-on,
since 1947 (which includes those "B+" high-working-voltage
electrolytics lots are so "afraid of" nowadays), I've been through
the same two boo-boos you mentioned...but only a few times and
that was long ago.

I've got a few electrolytics that have been around since the year
dot in the workshop and they still measure good enough, with
or without this "re-forming." Those were obtained some time
between 1958 and 1964, putting them 46 to 40 years ago since
first manufactured. :-)

No explosions, no going "poooof," just sitting there doing their
thing, tack-soldered into a quasi-breadboard for a hybrid "B+"
supply that is regulated and I'm interested in trading off how
much capacity needed for achieving a reasonable regulator.
Not building a production prototype, not worried about a job if
10,000 ordered parts will be scrapped if the wrong thing is
ordered or worried about future QC shouting and hollering about
"failure rates." It works or it don't.

This is a HOMEBREWER newsgroup. We aren't building space-
craft that must operate unattended on Mars. We should have
- as hobbyists on the bench - some kind of power supply handy.
It's a bloody simple task to just get some clip leads and a handy
series resistor and roll up some voltage from whatever supply is
there, then see if the electrolytics can hack it. Takes at most
a half hour to set up, do it, make notes, take down...about the
time needed for some to sit and agonize over problems they
don't have yet on the Internet. Geez, at worst, a cap will get
fried and a new one has to be bought. Maybe. One #$%^!!!
better than "replacing _all_ 'old' ones" as another suggested.

>free!

Actually, solar panels DO - under circumstances, but that seems
beside the point in this particular thread. We all get a migration
from the original thread question to automobile economy (!) and a
lot of polarized opinions. :-)

It seems that the higher the polarization level, the more they
become like electrolytic capacitors. Put them in the wrong way
and they blow up...

The original thread question (maybe) was about using solar
cells for battery charging. In that case there needs to be
identification with two major application areas:

1. The characteristics necessary to charge a particular battery.

2. The range of input voltage and current sufficient to operate
the charging circuit as obtained from solar cells.

Nobody seems to have addressed item (1) which would seem
to drive the whole task. Item (2) could have been satisfied with
actual measurements in a 48-hour time period, one day to set
it up, a second day to take the measurements, noting time of
day, cloud cover, etc.

Please excuse me for thinking linearly... :-)

You have to take into account that the cost of a kWh from
the grid in 25 years will be a LOT higher too, if there
still is a grid during and after WW3 that is.

I would say that so far during WW# there is still a grid.

Hi BR,

Thank you for the info. Today I connected the transmitter data pin to my square wave generator with a 1Khz square wave (at 3V peak) and I could see it on the receiver output pins, both the linear and digital pins on the receiver output pretty much the same signal. The only thing I was confused about is that, when I first switch the receiver on, the digital output is quiet (it goes to 5volts at first and then drops to and stays at zero volts). Once I transmit the square wave to it and turn the transmitter off, the digital output is very noisy (low frequency, I think) and never settles back to zero. The linear line comes up to about 2 volts on power up, shows a pretty good square wave when the transmitter is on and then goes back to the 2 volt level when the transmitter is turned off and stays much quieter.

I can probly filter out the noise on the digital line, or capacitively couple the linear line to get rid of the dc, but I still need to study this more. The range was amazing! I measured about 60 feet (~20meters) and the signal was still strong. This was with the receiver in a building and the transmitter outside. I can still get more range out of it I am sure, so I will be testing that also.

I have never worked with phase lock loops before, but I do have a few in my cmos collection, along with the data sheets. Do you know of any links I can visit to see some applications of the cd4046B PLL?

Thanks,
Joe

500' teflon insulated, silver plated, stranded 24 AWG.
Five 100 foot rolls in five different colors.
No choice of colors. No other gauges

$10 for 500 foot assortment. Shipping in US $5.50

Shipping in Canada/Europe $6.

For US only: up to 3 assortments (1500' total) same shipping rate $5.50
Total cost for 3 x 500' assortments $35.50 shipped in US.

Paypal OK.

Jack/All

Thanks very much for the tips. I have already decided to purchase the QST's I'm looking for on CDROM. I wonder if CQ offers back issues in electronic format...I'd have to bop over to their web site and see.

Which of course is a possibility when replacing them. So the restorer could be causing a problem where there was noeIf you want to carte blance replace them, that's fine, but I'm fine with taking a few hours to reform them. Generally if there is anything really wrong with the caps, it'll show up quickly.

> SUV or a truck or whatever, it's whether or not it's a gas guzzler.

A van with 4X4 or allwheel drive and ground clearance is an SUV.
Gas mileage becomes secondary if every time you try to move you get stuck.
The small SUV hold a family of 5 uncomfortably the larger hold a family of
seven, mom, dad, grandma and grandpa + 2 or more kids comfortably plus will
pull that 30'+ mobile home they camp in. Again not everyone lives in
Southern California where you can't do anything fun least you violate some
environmentalists dream.

Personally I bought the smallest vehicle I felt could do the job I needed it
to. That turned out to be a V6 that get about 25mpg highway.

Charles

Hi Jan-Martin,

Doesn't seem like anyone has answered this--hope you're still
monitoring it for followups.

There was an article in the Nov 2001 "Electronics World" starting on
page 842, "Active RF Scope Probe," using a Maxim MAX4005. It's a
high-input-impedance unity-voltage-gain amplifier with a built-in 75
ohm source resistor. The probe design puts a little attenuation ahead
of that amplifier, probably mostly for protection in case you connect
to too large a voltage, and there's 6dB loss in the termination on the
far end of the transmission line; so the probe circuit adds a 10dB op
amp gain stage. I haven't read all the details but believe it's
designed for 100MHz bandwidth. He has it AC coupled, but it could
probably be DC coupled if you wanted.

Cheers,
Tom

Solar Guppy wrote:
>
> And what does a 2 kWh system cost 15,000 mean ?

What it says. You buy (not build) a complete
2 kW system for $15,000. See below

> is that what you paid or

No. There was a long thread in alt.engineering.electrical
discussing this - it's the price mentioned by a guy in
Maine for a commercial system. There's a guy off grid in
California who built his own, like you did. His cost for
solar + inverter, not including batteries & DC instrumentation,
was about 10K for 4 kW. See the site for details:
http://www.electronconnection.com/Media/OurSystem.pdf

> just some made up numbers like your 16kWr per day which is pure fiction ..

Not "pure fiction". I clearly labeled it an assumption,
which is WAY different than "pure fiction". Here's
the quote, since you may have missed the first word:
"Assuming an average of 8 hours per day of 2kW per hour,
that solar system would give me 16 kWh. "

>
> I built my 6 kWh system for 17K ...

I don't doubt that. Your write up lends credence to
the much higher cost of a commercial system vs a
do-it-yourself system. You indicated it was very
labor intensive to build the first one, taking over
5 months of your spare time. A first time builder
would go well over the 6 days labor you cited on your
second build. In any event, the labor cost would be
borne in the purchase price of a commercial system.

>
> www.solar-guppy.com , you can see my invoices and the system installed in

> My average per day is about 24kWr/day so far (3 months) , my electrical
> rate is now 12 cents kWr (they have raised the rates about 2 cents kWh in

> the least year , more increases to come for sure)

Your average proves that my assumption is way too
high. Perhaps that's what you meant by "pure fiction".
Anyway, your 6 kW system produces 24kWhr/day in
Florida - I would expect lower if it was installed
here (in NY). And it means best case, a 2kW system
here would produce about 1/3 that or about 1/2 what
I assumed. That doubles the "payback" time - which
would never happen with the 2kW system at $15,000
here.

>
> 24 * .12 = 2.88 .. 17,000 / 2.88 = 5902 (days) = 16.17 years My , Real
> system , My real rates NO REBATES ...

And at $17,000 for the system, your mortgage cost
assuming 25 years, 7% will be over $36,000. Therefore,
your *real* payback is 36000/2.88 = 12500 (days) = 34.25
years. That assumes your system requires no replacement
parts, no regular maintenance costs, and does not degrade
over time, for the full 34 + years.

>
> Do the same thing in California , where 65 % of the cost is covered (50%

Use Solar Guppy's measured numbers and show us how
to take into account what you have in mind. I don't
know how to do it - I can't figure out what the
rates will be N, N+1, N+2 etc years from now.

But while you are talking about things "you have to
take into account": you have to take into account
the fact that most homes are not "solar friendly".
By that I mean that they can't get a full days sun
on the solar panels, due to neighbors trees, hills,
the house orientation on the lot, size of the lot,
etc. You have to take into account maintenance
costs for the solar system - it is totally unrealistic
to assume that the initial cost of the solar system
installation is all you will pay during the life
of the system. You also have to take into account
the degradation of the system capacity over time.

Hi Joe,
the receiver is probably a superregen type. Superregens are very noisy
with no carrier on their input. Superhet modules reduce the noise
problems, but they are more expensive and complicated.
I worked enough with 4046, but I have no link at hand. It comprises a
VCO and two phase comparators - you use only one of them. What I
remember:
1/ Set the tuning range of the VCO as necessary - not too wide, not
too narrow. Two resistors and a capacitor affect both the the central
frequency and the sweep. Check the tuning range with the loop open and
a variable control voltage applied.
2/ I always used the phase comparator No.2. The comparator No.1 (a XOR
gate in fact) usually did not give me satisfying results.
3/ The filter between the phase comparator output and the VCO control
input is essential for the dynamics of the PLL. Do not underestimate
its design.
IMHO for your purpose you should set the central frequency to the
frequency of the 555 at the transmitting side and a very narrow sweep.
If the proper signal is received, the PLL locks, which is indicated on
one of the 4046 pins. This is your "activated" signal. Otherwise the
VCO runs freely and the loop stays unlocked.

The DOS software you are refering to might be RF Tools, from Teledyne. It calculates attenuator values, Xc, Xl, resonant frequency, etc. If you do a search for RF Toolbox, you should be able to find the zip file. If you need a copy, let me know.

A high Q resonant circuit can be rather small.
For example, i made a tunable LC with a Q approaching 1000, and it was
not the size of a garbage can (resonant cavity); it was about 5 inches
tall and about 3 inches in diameter.
On one extreme, one uses standard LC parts and get fair Qs in small
size.
On the other extreme, one makes a ersonant cavity to get very high Qs
at the expense of size.
In between there is something that can be called either a "shielded
inductor" or a "resonant cavity with slow wave structure".
One takes an inductor and places it in the center of a metal cylinder;
one end of the inductor attaches to the inner wall (makes electrical
connection and acts as support).
The capacitance to the walls (and added ends) is the other half. Move
an end for fine tuning.
Rather ingenious; ther was an IEE paper 20 years(??) ago covering the
desigh equations.
The terminology used was "Helical resonator".

The instrument maker is a bloke in Nottingham. He's a radio ham, sadly a g7 who took the multiple guess exam.

He has made all sorts of stuff engineering wise. I've known him since he started makng different musical instruments.
A copy of a dobro metal guitar in stainless steel (he used two stainless steel sinks and soldering/welding (out of my depth here) the stainless was problem getting the right flux). Being the pedantic everything got to be right kind of bloke, (I'm a try this does it work , yes that'll do) He experimented with trying to put a transducer/pickup to amplfy the thing.

He bought some really expensive transducers and i loaned him one that was from maplins for 99p. There are two miracles here
1 it worked brilliantly
2 Maplins had some in stock.

I enjoy trying to play music but i have van goffs ear for music. (and stevie wonders eye for spelling)

Keep the good work.

Regards Ron

The trouble with software calculating tools is one doesn't know whether one
has the correct answer or not. Rubbish in - rubbish out!

Nothing can replace an understanding of what is to be done and a pocket
calculator.

It may be of interest -

Doubling the length and diameter of a solenoid and reducing the number of turns of thicker wire to maintain the same inductance, doubles the Q until radiation loss resistance begins to predominate.

And it's a big coil for radiation resistance to predominate.

Reg, G4FGQ

Hi, Joe -

I think the linear output is from the detector in the receiver while the
digital output is following an amplifier with AGC (automatic gain control).
If so, then you may find that the linear output will decrease in amplitude
with distance but the digital output will stay constant until the range is
so great that the signal drops into the noise. Using the decoder on the
digital output eliminates the noise you see when the transmitter is off.

Sounds like a fun project.

John

> This is only 1.6/1.1 times and not double, especially when considering
> highway driving instead of city driving. This means you can purchase
> a vehicle with good fuel efficiency without buying a Prius or even
> a hybrid.

Most people have a passenger car typical of a Toyota Camry, typically a
6Cyl auto trans that gets mileage in the mid 20s. (you can select yours
here http://www.fueleconomy.gov/feg/findacar.htm)

But the percentage of people driving passenger cars is dwindling, more
and more are driving SUVs and trucks. Those get even worse mileage.
One of my coworkers bought a new Toyota Highlander 4WD which is based on
the Camry and it gets even less (she says less than 20) than her 2 year
old 2WD highlander. Another coworker gets less than 20 MPG on a Chevy
Tahoe SUV.

So the Prius gets even _better_ than double the average vehicle MPG.
The Honda hybrids do even better.

Looking at the difference between the hybrids and SUVs, it's more like 3
to 1 better mileage, and that's mothing to sneeze at!

[snip]

> You could chose to eliminate chicken as well as beef, eggs and dairy.
> I'm no expert in either nutrition or food prices but I think you could
[snip]

The price penalty becomes even greater when you purchase food products
that eliminate meat such as silk and soy bean and tofu meat substitutes.
It's a matter of supply and demand; most people don't buy these things,
so the prices are higher.

[snip]

My apt. owner put solar water heater panels on the roof more than ten
years ago, and I don't think they've been cost effective. The
neighborhood vandals threw rocks at one and broke it, so they had to pur

chicken wire over the panels to prevent damage. The cats used the foam pipe insulation to sharpen their claws, so it's gone for about two feet up from the roof. The controller and storage tanks are not working as they should, so I would guess that the system needs repair. All in all, even with the rebates, it wasn't as good as it was made out to be.

I think that the figures that you gave might be optimum, but not realistic, when other things are considered. Like dirt and snow can seriously reduce the solar output. So some maintenance has to be done. And there are other factors, intangibles, that have to be considered, such as breakdown on the electronics. When that happens, the owner may have to make a tough decision to spend a lot of money to repair, or just leave it unrepaired and disconnect it. Don't say that's not going to happen! Most of the solar heater panels I've seen are not working after a few years. It's a just matter of entropy. Things just get ignored and turn to dust, and no one bothers with them anymore.

BTW, your followup is not easily readable, misuse of commas, etc. Needs work.

Coaxial ceramic resonators are cool... they are small, extremely
stable, and have Qs in the thousands.

The price penalty is only on items that try to replace or substitute
for meat (and often failing miserably). If you simply purchase items
such as beans, rice, grains, nuts and so forth, as they exist in
nature (or at least, supermarket shelves) then their prices become very
low.

You can always find the most expensive or least energy efficient way
of doing something but that doesn't mean that is the only, or even the
most common, method in use.

In the 80's there were a lot of government rebate programs to promote the use of solar water heaters. This gave rise to many installers who existed simply to exploit the rebates and as a result they installed shoddy equipment and gave buyers unrealistic expectations. Once the government rebates dried up these predatory companies disappeared and their warranties along with them. This is why there was such a glut of broken down solar water heaters and people completely dissatisfied with the entire idea. This doesn't mean that they can't be cost effective. I've seen many solar water heaters that have been in continuous use for 20+ years with only minimal maintenance and the owners of these appear to be satisfied.

In fact, we had one of these installed around 1980, just after the Feds started the rebate program and my late wife's dad died, leaving her a bunch'o'bucks. It worked _very_ well indeed until June 2002, when it died catastrophically, leaking water in a proprietary fitting, just after we got back from Canada. It gave yeoman service up to then, and if I could find someone with the parts, I'd put it back in service again. It was _really_ nice to have 300 gallons of hot water _and_ forced-air heating to all the rooms in the house. Now we're back to a floor furnace.

The only thing I had to do in all those 20+ years was install a switch to sense loss of water pressure and turn off the recirc pump for the silicone oil, so that it wouldn't overheat and decompose because it didn't see cool water in the heat exchanger. After a little bit of cut and try, the plumber and I got that working just fine.

Oh, and we did actually wear out (water flow around a bend in a tube finally wore through the tube wall) a heat exchanger, but that was replaced under warranty.

I miss it.

ehsjr@bellatlantic.net wrote in <407F7FE6.3D9FC215@bellatlantic.net>:

>ou also have to take into account
>the degradation of the system capacity over time.
That would be 80% of capacity I think.
And yes, you could take the kWh price of 25 years ago,
that of today, and draw a line, it will point up,
extrapolate to + 25 years from now ,and you have a value.
The other thing that will help is the inflation, you
can roughly say that money halves in value every 10 years.
This has 2 effects, now, if you did have a loan for the solar
cells, and you pay 2% of your income, in 10 years this will be
only .5 % and in 25 years the amount you have to pay will look
ridiculously low.
From this we can see that borrowing is not a bad idea perhaps.
Also that still leaves you with all the cash you can spend on
other things now.

Based on an earlier P.Burridge thread, I'd say that's NOT small for
him. Of course, you didn't mention the frequency (I'd guess around
10MHz), but in the earlier thread, I was suggesting that he use a coil
at 18MHz or so with a Qu around 100, and he didn't seem to like even
the rather small size that one could make such a coil. I did it on,
um either a .68" OD or .80" OD powdered iron toroid, and that was
apparently too big. I also suggested a multi-pole filter which could
give the same effective filtering, and could use three small SMT
inductors. I gathered even that was too big. And I suppose coaxial
ceramic resonators for one-off projects at 18MHz aren't very
practical...

> On one extreme, one uses standard LC parts and get fair Qs in small

> On the other extreme, one makes a ersonant cavity to get very high Qs
> at the expense of size.
> In between there is something that can be called either a "shielded
> inductor" or a "resonant cavity with slow wave structure".

There seems to be a popular misconception that a helical resonator
gives better Q than an unshielded coil and capacitor. One of the key
nice things about helical resonators is that they are well
shielded...there's extremely little external field. That lets you
stack several of them side-by-side, with appropriately chosen coupling
apertures between the cavities, to make a nice, compact multi-pole
filter. But let's not assign a quality that isn't there: the same
coil WITHOUT the shield will have a higher Qu, so long as it's not so
huge that radiation is a significant loss mechanism, and as Reg
suggests, that's BIG for most of the tanks we think about. In the
older editions of "Reference Data for Radio Engineers," e.g. the fifth
edition, there are some design nomographs for helical resonators in
the Transmission Lines chapter. They will give you the Qu. If you
find the Qu of the coil in air (see the same book, Fundamentals of
Networks chapter, or use Reg's coil program or WAIRCOIL), you'll see
that the coil's Qu is higher. And if you look also in the Fund. of
Networks chapter, you'll find a graph for the decrease of inductance

of a coil when shielded, and you'll find that that almost exactly accounts for the Q lowering: same effective series resistance, but lower inductance, gives lower Q. Is it significant? Well, I think for a typical helical resonator, it's a 15% to 25% lowering.

Mainly I want to dispell the notion that a helical resonator is something magic that _raises_ the Q of a given coil, because it's not. It does have some very nice properties, but that just isn't one of them.

Early helical resonator reference: W. W. Macalpine and R. O. Schildknecht, "Coaxial Resonators with Helical Inner Conductor," Proc. of the IRE, Dec. 1959 -- almost 45 years ago now.

Cheers,
Tom

Tom,
thanks for reply.

I received a few replies replies via mail, but they seem to have misunderstood the points in some degree, one outlined a theoretical circuit which should cover up to 900MHz using general purpose devices and made no notes to whether it was an improvement over my suggestion or not.

Suppose your device could be what I was looking for and will check it out later. It is not really so imprortant which attenuation you get as long you know what you are doing. In the first case I need only 20MHz bandwidth, while 100MHz or more seems interesting for other later purposes like RF millivoltmeter. The first instrument is used with a selective voltmeter, which might be connected to converter for larger frequency range that 0.005-17.2MHz later.

I've already made one mV-meter using germanium diodes (AA119 or 1N270's) which covers up to 2GHz, but minimum reliable reading is for 10...30mV RMS, and an improvement here is very much desired.. The RF millivoltmeter is described as item 10 on the same page. A problem is that it was built 20 years ago, and the mechanical construction now

seem to cause some problems and a new meter seems to be required soon.

So now you saying solar thermal has no pay back ? ... please ... solar thermal is about 5x better than solar PV in payback times.

The cost is about 1700.00 (US) for a system that will replace about 90% of domestic hot-water needs , and in my last house , lowered my electric usage by about 45 dollars a month.

There are many web-references to the 3-4 year break even ... instead of picking on my grammar , spend some time to get your facts right and use Google for references instead of your obvious fact-less opinions of solar thermal and solar electric.

Hi John,

Yes, it is fun. Looks like I will be learning about PLLs too. By the decoder do you mean the holtek? I was not going to use the encoder and decoder, since this is not a really critical application. I was planning on generating a square wave with a 555 at the transmitter data pin and then when the receiver detects it, take a picture. Yes, I think you are right about the linear pin, because I noticed the magnitude of the received signal seemed to drop a little with distance, but the digital pin stayed strong the whole distance when I moved the transmitter from it. The linear pin seems to be much quieter tho.

I still haven't worked on this yet today, so off I go to work on it some more and maybe I can get a working circuit soon.

Regards,
Joe

That's fascinating.

I only sort of glanced at the original message, noticing it was
AM, but I was reading SPAT as SPRAT, and while I can't remember
what the latter stands for, I thought it was a ham QRP group.
From that perspective, the message almost seems misleading.
I wouldn't have entered, but I wouldn't have given a thought
to the post without your message.

The time proven method uses wire wound power resistors, with somewhat
lower values (higher wattage). For 450 volt caps resistors in the 50k
range are common, this will require 5 watt resistors (use 10w to be
safe). The higher bleed current serves two purposes, it discharges the
capacitors when the power is shut off more quickly, and reduces the
peak voltage reached protecting the capacitors. High voltage capacitor
strings using higher value resistors can hold a charge for several
minutes, a hazard for the careless!

> other things now.
> JP

Your figures are off, and are unrealistic. You said money
halves in value in ten years, yet you mention 2% today
and .5% ten years from now, a factor of 4, not 2.
And using the numbers: 2% of one's salary to pay off a $17K
mortgage over 25 years works out to an annual salary of
$72,000. Most people making that kind of money are at
the high end already, and won't see the same kind of
percentage increases that people starting out will see.
It is unrealistic to think that, on average, people making
$72,000 today will be making $144,000 ten years from now.
If they are already making $72,000, they are also likely
older, (maybe 60 as a guess) and won't live to see the
payback, if it does come.

What is needed to make solar economically viable for the
masses is a drastic reduction in the cost of solar - or
a huge price increase in the cost of utility provided
power. That does not mean that there are no individual
cases today where solar is attractive economically, nor
does it encompass those who can't connect to the grid.
But it's a non-starter for better than 99 percent of the
people who can connect to the grid. The number of

people who are grid connected and are economically ahead with solar is exceedingly small. Even Solar Guppy, who clearly has expertise in this area, posts a 16+ year payback period - and that's without considering mortgage, degradation, maintenance etc. over time.

Investing in solar today, with the concept of breaking even 34 years down the road, is an asinine financial move. Betting on an earlier computed break-even point due to rising energy cost is damn near a sure thing - but still an asinine financial move, unless you have some idea of when the break-even point will be. In most cases, when you run the numbers, you'd be better off playing black jack at the casino. At least there you have a close to 50% chance of winning. For most people who run the numbers, solar is clearly a no win situation.

I wish proponents of solar would be more like Solar Guppy, or the guy in california at the site I posted. They lay it out, based on actual measurements. The guy in California is WAY ahead of the game, because it would have cost him about $90,000 to connect to the grid. He itemizes his entire system - solar, wind, hydro - with the price of everything. Solar told us his system cost, capability and price per utility generated kWh, and provides good info on his site. If you haven't been to their sites, I recommend taking a look.

Yes, but the emphasis was on small size, and a helical resonator
allows a goodly shrinkage of volume wihout a corresponding loss large of
Q.
But if the frequency is low enough, the ferite core method, if
properly wound, then becomes a "preferred" solution for small size and
high Q.
Maybe his requirements are not too realistic?

A resonant cavity for the FM band would be roughly the size of a
garbage can (which i stated); 6 inches is slightly smaller, i think.

3057. HP680 Chart Recorder

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-17 08:32:59 UTC

Does anyone know of a web site where I could access a copy of a tech manual for this chart recorder, I've had a quick search but nothing obvious comes up ? I've saved a couple of units from being trashed, cleaned them up & got them working but they're a variant that uses an electrical contact type of pen. I'd like to convert this to an ink pen and have some ideas as to how I can do it but I'd also be interested in knowing the HP arrangement.

Particularly interested in knowing where HP mounted the ink reservoir, was it on the moving carriage that carried the pen or is it on the fixed body of the recorder ? Maybe someone has had experience of using this equipment and can describe the arrangement they saw when refilling the ink reservoir. Or did HP use disposable ink cartridges ?

Source record: 26748

Hi.

Since some time ago I cannot reach qsl.net on the net. I used
http://visualroute.visualware.com/ to figure out what's happening and it
shows me:

"IP packets are being list past network 'UUNET Technologies, Inc. UUNET65'
at hop 8. VisualRoute cannot determine the next network at hop 9. Node
65.207.92.86 at hop 8 in network 'UUNET Technologies, Inc. UUNET65' reports
'The destination host is unreachable'".

It means is not my ISP problem, but a generic problem. Has anyone any idea
of what's happening ?

Thanks

Hern&#65533;n S&#65533;nchez

I have no idea what's in them, and not even a good idea of their
function (well obviously it's something to do with tv).

Assuming these are for use with cable, I suspect there is less of
interest in them than some other items, at least given the price.
Cable converters (ie they don't do descrambling but convert cable
channels down to where an old tv set getting channels 2 to 13 can
receive the channels) have a wideband converter, usually double
conversion, that have been used in some "spectrum analyzer" projects.
But I find those in the garbage (or did, maybe they have now become
too old).

VCRs have wideband tuners too, though the ones I've taken apart
tune in segments like tv tuners rather than all in one range like
the cable converters. VCRs are plentiful and free, and you can pull
pretty much all the plastic basic purpose transistors you need off
them. As long as it's older, then the components are not surface mount.
They are much cleaner than the TV sets that I noticed when I was a kid.
If I was starting out, I'd be pulling the resistors and capacitors off
the VCRs too.

I once found a satellite receiver waiting for the garbage outside
a repair place. Besides the nifty case, it came with a diode ring
mixer, I think with a known brand on it. I pulled some other things
off it, but it was less than I would have expected (though, I didn't
really have expectations).

Old cellphones, the big clunky kind, tend to have interesting parts,
and since we're talking old they are cheap since nobody wants them
and the parts are less integrated and often not surface mount. TCXO's,
FM-bandwidth crystal filters often in the "roofing filter" range, indeed

complete FM IF strips, UHF prescalers, NE570 companders or direct variants and if they are old enough, CPUs and their peripherals that are recognizable and reusable. I've bought old cellphones for as low as fifty cents, and have paid up to five dollars because I could expect a reasonable return.

What sort of parts are you looking for? That might help to solve whether something is worth actually paying for.

I'm not a kid, but I still carry tools around. And I think there's
a much better selection and quality of electronic junk being tossed
than when I was a kid.

Back then, over thirty years ago, you'd be lucky to find tv sets
and AC/DC radios. And the heat from the tubes tended to collect
all kinds of junk from the air (or maybe it was mainly because people
tended to keep such things in use for so long) so they were terribly
messy. And of course, the components tended to be big and bulky, though
of course since it was in the late tube-era that's the sort of thing
needed for building anyway.

I was out somewhere yesterday, and came across a monitor that had
a bunch of BNC connectors on it. If I hadn't been trying to get somewhere
on time, I would have taken the time to get them off. As it was, there
was no easy way to get that assembly off, so I left them there. I did pull
two boards off, one digital, to strip down later.

Having the tools is great. You can be selective. When you start out,
most of such equipment can be useful, but as the decades drag on, it's
too much trouble to bring the whole thing home. With tools you can
get the equipment open and extract useful parts right on the spot.
So you can pull the variable capacitors off any radio you see. Or
pop open that computer to pull out any memory. I've been grabbing
switching supplies from computers, partly because they are easy to
extract, and originally because I thought I'd reuse them as power
supplies. But there are more than enough for that, so I've started
pulling the boards out of the boxes when I get home, and using
the boxes for other things.

Ahaha! I did the same thing. I had a basement full of CRTs. Finally came the day to discard them, just lined 'em out on the street on garbage day. I didn't bother to break the seals. I was looking out my bedroom window as the trash collector tossed the first one around the back edge of the truck. It blew up! Nice cloud of white phosphor. He treated the rest of them like nitroglycerin. My Elmer told me how to break the seals so that wouldn't happen again.

I still get a fair share of parts from salvaged gear.
http://tinyurl.com/34np2 It just doesn't feel like homebrew otherwise. None of the pictured items remains intact.

Doing a run on QRZ.com, I am wondering if you were at this free flea? I live up in Stuart but I made it to this one. Passed on Hollywood today to finish a project, but I'm going to be in Gainesville next weekend.

FWIW, the HP plotters I used to see used short drafting pens with built-in
reservoirs. You might find those on eBay. The problem is the mass of the
pen, but if you aren't charting fast-changing data that may not be serious.
This eBay auction has a drawing of the pen I'm referring to:

Tom,
thanks for reply.

I received a few replies replies via mail, but they seem to have misunderstood the points in some degree, one outlined a theoretical circuit which should cover up to 900MHz using general purpose devices and made no notes to whether it was an improvement over my suggestion or not.

It seems your is the one I'd been looking for. It has 6dB loss, and when you add 4dB for protection it makes 10dB which is easy figure for measurements. It is not really so imprortant which attenuation you get as long you know what you are doing. In the first case I need only 20MHz bandwidth, while 100MHz or more seems interesting for other later purposes like RF millivoltmeter. The first instrument is used with a selective voltmeter, which might be connected to converter for larger frequency range that 0.005-17.2MHz later.

I've already made one mV-meter using germanium diodes (AA119 or 1N270's) which covers up to 2GHz, but minimum reliable reading is for 10...30mV RMS, and an improvement here is very much desired.. The RF millivoltmeter is described as item 10 on the same page. A problem is

that it was built 20 years ago, and the mechanical construction now
seem to cause some problems and a new meter seems to be required soon.

You must still account for the energy you extract from the circuit in order to measure the ringdown. Even the energy needed to drive a high impedance probe is significant when the Q gets high.

IOW, the Q without the probe will be higher than the Q when you insert the probe to measure the Q.

I was in the Xtal business for >20 years so can answer individual
questions.
WWII and before Xtals were flat plates and vibrated to the edges in "air
gap" holders.
after 1950s centre plated crystals were ideally dead at the edges.
If you want to lap frequencies up a VCO tuned comms receiver can pick up
the broad band noise generated and centered on the crystal frequency.
Above assume shear mode AT type or Z cut plates.

Of course, you can account for the probe loss when you do the math. Or
leave the probe disconnected during a ringdown, and add it after some
delay to see how much energy is left in the system.

BTW, I've found that a graph of L, C, F and X is very often more convenient and faster to use than a calculator, be it a general-purpose calculator or one specifically for L/C/F/X. Depending on the graph you use, it might well be accurate enough for engineering use...it's not difficult to read values to a very few percent, and you'll usually be hard pressed to find parts that meet that sort of tolerance and not require tuning to achieve the desired resonance anyway. The graphic presentation helps me visualize what's going on, just as a Smith chart helps me visualize the effects of components in a matching network, and that visualization is something I can't get from just numbers on a screen.

If you don't find such a graph, you can make your own from log-log graph paper. You then can put L and C on the x and y axes, and the lines of constant frequency and constant reactance become 45 degree diagonals; or you can put X and F on the axes and L and C become the diagonals. 3x3 decades is easy to use, if you are comfortable with mental scaling between pico, nano and micro. Or you can use 6x6 with lower resolution but less need to scale.

Cheers,
Tom

If you have to "do the math", you might as well just calculate the Q
from first principles and forget the "measurement".

Not so. And others have pointed that out. If you take an unshielded
coil to it's ultimate configuration you are confronted with a resonant antenna
that is loaded by its radiation resistance and that results in a *lower* Q than
a properly shielded resonator.

Ah, just the person I've been waiting for. How do you account for current bunching on the conductors (that is, non-uniform distribution of current around the conductors)? What reference, equation, or program do you use? Nearly all "first principle" calculations of Q I've seen grossly overestimate Q, and I believe the failure to take this into account is at least part of the reason. I haven't seen a decent analytical method of dealing with it, and an anxious to see how you do it.

Then there's surface corrosion and roughness, radiation, and coupling to nearby objects. How do you deal with those? Have you identified some of the other factors that often make a simplistic "first principle" calculation disagree so badly with carefully made measurements?

IIRC, the Marconi unit used a 10 nH inductor (maybe less) made of a
short length of silver wire, gold-plated to eliminate sulfide attack.
The effect on Q would be minimal in the extreme.

It's not that they're tricky to look at -- it's that they're tricky to
get everything working right.

This looks like it's a basically good design. It's common-source, which
is a bit odd. There's no buffer indicated, which will be necessary.
Really what makes VFO construction difficult is getting the thing stable
with respect to nearly every effect in the known universe, and that has
more to do with component selection and construction methods than it
does with the schematic.

If I were going to recommend a VFO I'd recommend a series-tuned
colpitts. You can probably find one in the ARRL handbook and build
away. If the designs look complicated it's because to be useful a VFO
needs the oscillator itself, a buffer amp and usually a power amp. The
schematic you have leaves off the buffer and power amplifiers; by the
time you stick those on your schematic will be as complex as any other
VFO design you've seen.

I can recall using one of those, some little time back. Anybody have
the schematic diagram for it?

And usually they have option too.....

>What is needed to make solar economically viable for the
>masses is a drastic reduction in the cost of solar - or
>a huge price increase in the cost of utility provided
>power.
That last thing will never happen.
I agree the solar cells need to be mass-produced and then
will become cheaper.
Recent research now found a way to double the efficiency to
35 % or more, but these are not in production.

> That does not mean that there are no individual
>cases today where solar is attractive economically, nor
>does it encompass those who can't connect to the grid.
Here in teh Netherlands where i am, you could get the
solar installation almost for free, because of government grants,
so many people did it that the gov ran out of the allocated budget,
and is now drastically reducing subsidizing solar power.

>But it's a non-starter for better than 99 percent of the

>degradation, maintenance etc. over time.
If you get it 4 free, payback starts immediatly.
Problem is that in teh old electricity meters the meter
would run backards, and you got a lot for a kWh into the grid.
Now the power companies fixed that by using electronic meters that
will not run backwars.. clever!, but you can become a 'certified
electricity supplier' or something (I am not, just what I did read),
for 250 Euro or so a year, and then ge t7 Eurocent for a kWh so no
good deal, only costs money.
The solution is IMO to ge tsome large lead acid batteries, keep thse
warm somehow (does not work if -10 C), and use those to cover night
and non-sunny times.
And disconnect from the grid altogether.
For sci.electronics.design, 25 old car batteries gives 300 V DC at
100 A/h, big H bridge and make a nice 50 Hz sine at 240 V..
Maybe I am dreaming.
Unfortunatly there is not a lot of sun here...

>Investing in solar today, with the concept of breaking

According to some discussion on the linux-hams mailing list, QSL.NET
had a problem a short while ago - their system was being attacked by
"crackers" located somewhere in South America - Brazil, I believe. If
I understand the situation correctly, they were unable to get support
or assistance from ISP(s) from which the attacks were originating. As
a result, they have apparently started blocking inbound TCP/IP traffic
to their site from a significant portion of South America.

Sourcing INTO the power grid is also supported in Arizona. Apparently
there are a few customers here who produce more than their own
consumption and get PAID every month. (Not difficult at all if you
own at least an acre of property.)

The Crystal grinding shop in the Washington DC Navy Yard (1947) had a
National HRO receiver
connected to the rough grinding machine. They picked up the noise to
tell how near to the finished
frequency they were. They then went to hand grinding to finish.

I have a chunk of Quartz from that shop.

As I kid I would explore the neighborhood on my bicycle on the days
the trash went out looking for junk TV sets. I had a set of tools
in my pockets to pull out the chassis and would lug them home to
gut. A friend of mine who lived in a house instead of an apartment
would save the chassis whole in the basement (which bugged the
gas man who had to climb over a mountain of tv chassis to read
the gas meter!).

I was responding to a suggestion that one could do the math to calculate
what the Q would have been if you hadn't tried to measure it. I was pointing
out that if you could do that math, and get it correct, that you could do the
whole exercise with math and forget measuring anything.

And how do you know for sure that calculations overestimate Q when
measuring Q to verify the calculations disturbs the very thing you're measuring?

An engineer knows when to say "close enough". A mathematician is never
satisfied.

But what about the energy extracted from the probe to make the
measurement? Any load on the probe is transformed into a load on the resonator.
Compensating for that load requires a very small number be divided by another
very small number. Any error in either number makes a much larger error in the
result of the calculation.

==========
As a rule of thumb , a starting angle (from horizontal) for setting up a
solar panel is Degrees Latitude plus 10 degrees.
My QTH is at 57 degrees north ,so I have initially set up the 2 panels
(each fitted at ground level on an adjustable hinged wooden frame) at
approx 67 degrees. , pointing due south ,which is about optimal (not having
a tracking system)
I use 2 make: Unisolar ,64Wp panels which have a non or low reflecting
surface made of a polymer (no glass).
Rated output per panel 3.88 Amperes at 16.5 volts ; short circuit current
6.3 Amperes.
Charging 12 V Lead -Acid batteries to 14.4 V , voltage limited by a home
made shunt controller .
System includes a 150 Watts wind generator , to support system during windy
(and usually sunless) periods
Purpose : Amateur Radio station with peripherals including 12 V halogen
bulbs desk lighting.

Now a wind generator would be cool, there are many windmils of huge size here,
one next to my house (100m or so), a BIG one that replaced 5 smaller ones...
It is on the coast, and it is always windy here...
How big is that thing?

Have you seen the windmill "farm" west of Indio, California (on I10) ?

HUNDREDS of large windmill AC generators.

From the Belden site.

899907 which is 9907 will handle from

4500W at 2Mhz
260W at 1Ghz

So yes, you have 950 ft of RG-58 size coax. See the Belden site for more info on the losses at specific frequencies.

Jeff, KC9EII

Thank you for your input, I've got a brand new rig on the way and my old 5/8 wave mount has coax chafed to the point of braids of shielding showing. I thought the 9907 would work, but wanted more opinions before I burnt up a brand new rig to High SWR. Once again Thanks!

I've measured quite a number of inductors both with a homebrew setup, in which I account for the losses in the input and output networks, and with an HP Q meter of specified accuracy. With simple input and output networks consisting of a small series C and shunt R, the effect on Q is predictable and easy to calculate. Results from the two methods agree quite closely, even though they use somewhat different methods to arrive at the Q, giving a fair amount of confidence in both results. And both disagree quite dramatically in some cases to Q calculated simply from theoretical calculations which include only conductor resistance (including skin effect, of course), inductance, and shunt capacitance. This is with inductors of only moderate Q -- calculation of very high Q inductors, which is being discussed here, would require more attention to second order effects -- as would measurement.

Thanks for the profound observation about mathematicians and engineers. In which category does one put a person who's satisfied with calculations made without thinking about, caring about, or considering the errors caused by ignoring fundamental effects? Certainly not an engineer as I use the term.

I don't blame you for being paranoid about WW3, if you're from Holland.
History has treated those countries poorly during the last WWs. But
then, who cares if there's a WW3? I'm more concerned about the next big
earthquake. Some scientists are predicting a big 6.something earthquake
in the Southern Calif. desert before Sept. I hope so, 'cause some of
these immigrants might consider going back to their point of
origination.

Last I checked, nuts were more expensive than some meats. And most
people haven't got a clue as to how to eat a meat-free diet and get
proper nutrition. That's the problem.

Well, the question is, did the gov't get what it wanted, with the
subsidies that it did hand out? In other words, did it hand out 100
million Quatloos worth of subsidies, and get back _more_ than 100
million in benefits, such as reduction in the amount of non-renewable
energy usage, etc.

If so, then it seems to me that the program served its purpose and
should be continued, and even broadened. But then politics..

Please then state your facts .. did your landlord share this with you ?

what was the cost ? ,
what amount of hot water does or did the system produce ?
how many years has it produced hot water ?

and how about some simple numbers to back-up your claim it didn't have an
economical payback ...

http://www3.sympatico.ca/hipett/hotwater.htm 3-4 year payback
http://www.solagen.com/water-heating.htm 1-3 year payback
http://www.environment.act.gov.au/Files/solarhotwatersystemsreport.pdf 4-6
years (in AU dollars)
http://www.ecs-solar.com/solarhotwater_faq.htm 3-4 year based on 600-700
year savings
http://www.solardev.com/hot-water-types.php 4-7 years
http://www.uneptie.org/energy/act/re/fact_sheet/docs/thermal.PDF 4 - 14
years (I guess you can pay to much for anything)
http://www.sixriverssolar.com/solar_water_heating.htm 4 -8 years

Every hear of Google ?

most of the above links are a bit outdated , and if today's electric/Natural
gas prices were used , payback for a self installed system would be in the
2-3 year range. (based on a 1600.00 kit , that I having bought and installed
, replacing 600.00 year in electricity.) I bought and installed and used
this system for 2.5 years ... what are your numbers NOSPAM ?

Well, then don't buy more expensive products and educate yourself
about proper nutrition. It's not like this is especially complex or
the information particularly difficult to find.

==========
As I reported in a previous message its rated capacity is only 150 Watts.
6 Blades , 900 mm diameter, max rpm approx 250 , 3 phase generator (DC
through one and a half standard 25 Amperes bridge rectifiers)
The thing sits on a street lamp post with an extension (approx 8 metres
above ground.

Large pieces of natural quartz usually from Brazil are getting rare as
quarts gravel/pebbles are now used as feed material for re-growth on a
seed plate in autoclaves.
If large slices in the Y direction are required (SAW DELAY LINES) growth
in this direction is so slow that the seed has to be from a slice of
natural.
Hence big natural pieces are valuable.

The sensing inductor was connected to the grid of a triode tube, with,
IIRC, a 1 Mohm grid leak. With 1 mV across the sensor, that's a whole
1 uJ/s of energy extraction.

>Any load on the probe is transformed into a load on the resonator.

Check your math. It's small errors in *differences*, not in ratios, that
result in large errors in results.

It's an unusual place- the wind just whistles through the canyons
there and there are dust stoms. A fair number of them seem to be down
for maintenance whenever I go through. I wonder if it is really more
cost effective than burning coal.

Best regards,
Spehro Pefhany

ONLY if it's really big. See Reg's posting in this thread on that
subject. We're talking about making things small here, like smaller
than a 1 inch diameter coil at 18MHz. The cavity for a standard
helical resonator design will ding the Q by 15% or more; for such a
small unshielded coil do you expect that much radiation? I don't.
Not even close.

Cheers,
Tom

I think I several hours building mine from an ARRL handbook design of some sort, then maybe a half hour a day for a couple of weeks with a 50 Watt lamp for heating and a fan for cooling until I tweaked the drift with various N750, etc. ceramic caps. A real challenge but whatever drift I have now is virtually nil . I think I quit tweaking at about 200 Hz "cold" to "warm" drift. BTW, my transmitter is a hetrodyne affair, 5.0 to 5.2 MHz VFO + keyed crystal oscillator, both feeding Mini-Circuits DBM.
If you are interested, I can put to schematic what I ended up with as I need to do it anyways for my own reference.

Such a person as you describe is commonly known as a physicist. I have
had to work with several. That some of them are still alive is a testament to
my degree of self control.

There'a an article in the May 1986 QEX titled "A Bridge Method of Sweep-Frequency Impedance Measurement" by W3UB. My QEX collection is missing this issue and I wonder if anyone has a scan they can provide me?
tnx

Thanks... I think this is the answer... I live in South America (Colombia).
Do you know how can I contact QSL.NET to help me with access there ? any
QSL.NET mirror ? I'm a ham radio and QSL.NET is an excellent source of
ideas.

Thanks

LOL! But physicists are usually *preoccupied* with fundamental effects
and tend to ignore others.

In my brief skirmish with aeronautical engineering, I formed the opinion
that most of the calculations were as pragmatic as RL suggests; the only
consolation is that they seem to work.

That's silly economics. I do not have to take into account the
cost of electricity in 25 years. I can wait. Solar cells are
becoming cheaper too. When the cost of the solar cell is less
than the cost of power from the grid I can switch, saving all of
the negative amortization inbetween, and have a *new* system in
25 years, just as you're in need of replacing yours. ;-)

My guess though, is that solar cells for the individual will
never become cheaper than power from the grid, since the power
company has access to the same technology and a *lot* better
financing possibilities. ...and they don't have to have the pay-
back in my lifetime.

Wrong again, as first hand experience working in California
I KNOW how it is.
I ALSO know what a jail full of illegal Mexicans looks like from the inside.
So you better stop joking, I probably know US better then you.
And no I am not a Mexican.
That was the south border, I can also tell you about the north border.
Now go and dream on, dream dream dream the US dream my friend.

A guess it is, given that solar cell efficiancy will eventually reach 60 %
in my estimate, then yes, buy one like that in your next lifetime if you
believe in that stuff.
In the mean time there are thoso who use them now.
When the US gets a real oil problem, you can always get one at crisis price.

> HUNDREDS of large windmill AC generators.

Is that the farm between LA and (around) Palm Springs? I drove
through there ~five years ago and was amazed at the size of the
wind-farm(s?) and the number of turbines that were stopped.

I believe the name of that farm is "San Gorgonio Pass" and has
about 3500 turbines. The "Altimont Pass" farm has another 3500
and an even larger one in "Tehachapi Pass" (5000). (there is a
common thread in these names ;-)

Altogether something like 1% of CA's electricity comes from wind.
That's impressive, though hardly scale able to 100%. The CA
mountain passes hardly indicate the viability of wind power in
the rest of the country/world.

I haven't been able to determine if the stopped units were off-line
for repair, or simply off-line based on grid needs. I've *never* seen
anyone *working* on them, but I drive by there only once or twice a
year.

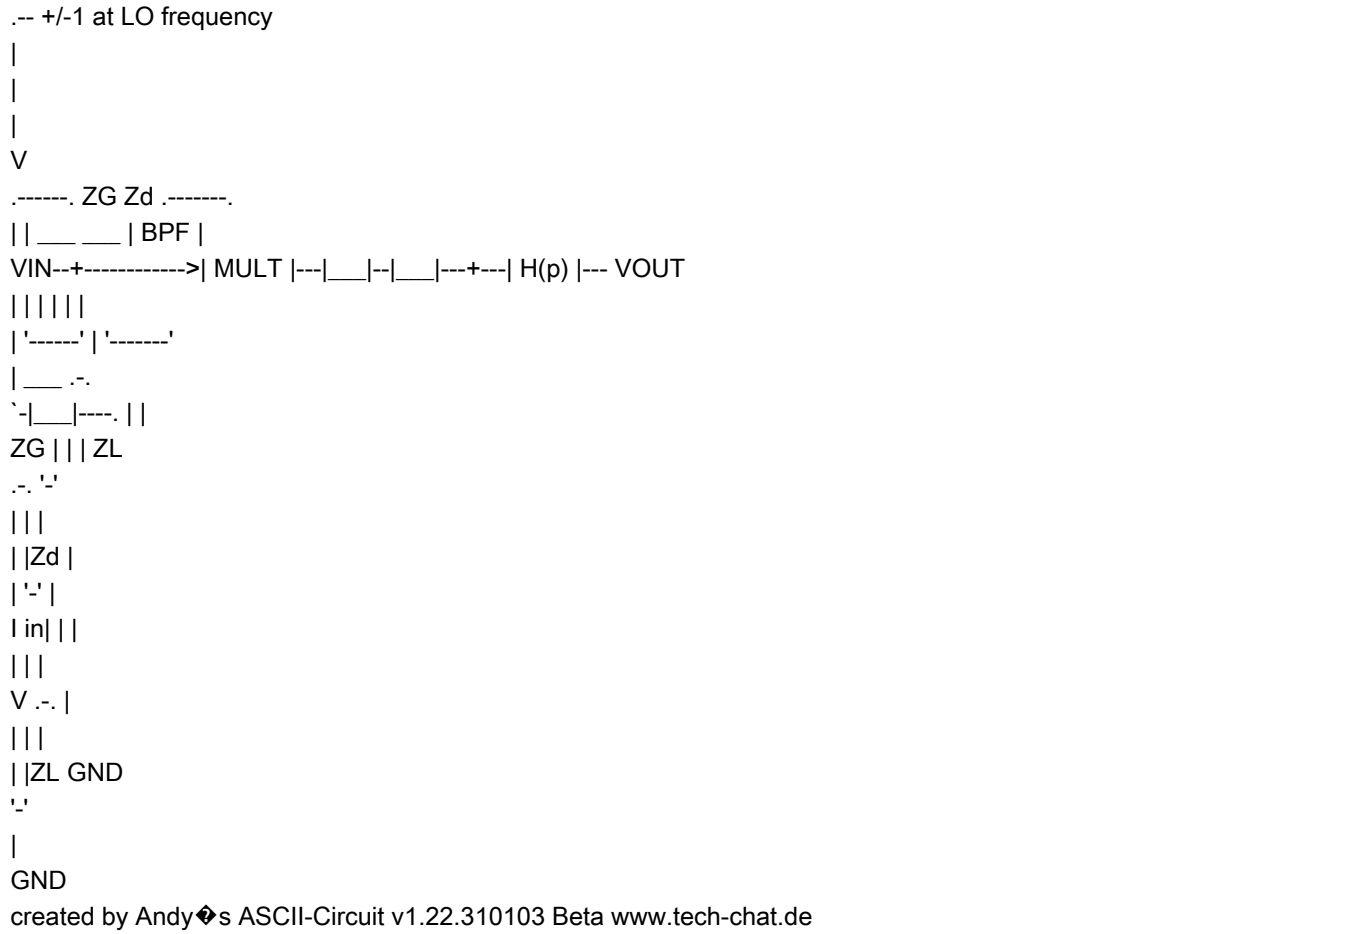
Hello,

I have to use some DBMs in a measurement instrument and of course have to design the following bp filters.

I have often seen recommended that the DBMs see the resistive load of a constant R filter (diplexer) rather that the reactive load of a more traditional filter.

I can think of (model) the DBM mixer to the first order as follows :



ZG being the source impedance,
Zd the diode dynamic resistance,
ZL the filter input impedance,
H(p) the BPF voltage transfer function.
The multiplier is a high Zin, null Zout device with unity gain.

I can't see any requirement in this first order model for a constant R load.

Do I miss something ? Is it needed because of second order effects ?
Any thought, any pointer to (preferably) detailed analysis is welcomed.

Thanks,
Fred.

The math in question is trivial. Qs from 1 to 1e9 can be measured
accurately without difficulty.

But then, mathematicians don't measure things, do they?

Hern&#65533;n

There are a number of sites that allow you to browse other sites. The idea here is to hide what sites you are browsing by connecting to the websites from an address other than your own. They should be able to help you out by stepping around the problem.

www.anonymizer.com is one of these, but there are tons of others. I haven't actually used any of them so I can't tell you if one is better than another. I did put a qsl.net address into anonymizer.com and didn't like what I saw. But if you poke anonymous browsing into google you'll get a zillion sites to try.

From my conversations with wind-energy proponents after seeing
the farm, they seem to be off-line for maintenance, and the
required maintenance wasn't deemed profitable. No subsidies for
maintenance, only development. This may have changed since the
generators have become cheaper, perhaps even profitable. ;-)

Mike:
The COAX isn't going to be a cause for your new rig to burn up - but a high SWR might (although the rig should shut down first). The question was "will it handle the power," and apparently it will. Assuming that and a well matched rig/coax/antenna combination - you will have no problems.

You could probably contact them by using any of several Web-based email services - e.g. Yahoo.com or similar ones. Create yourself a free account and use it to email QSL.NET - since the email itself will originate at the webmail service's IP address it won't be blocked.

I don't know of any QSL.NET mirrors - it's a self-funded and donation-funded operation and I don't think anyone has volunteered to provide a mirror.

You could probably access it semi-indirectly, by using one of the various "anonymous web surfing" proxy services scattered around the Net. [There are also about a bazillion wide-open web proxys running on poorly-configured or Trojan-exploited personal computers on numerous cable-modem and home-DSL networks, but using these without the owners' explicit permissions would be very bad form and is quite often a violation of one or another law.]

Nope. That's why I'm not investing for the next lifetime. Only
fools without an ounce of economic sense do so.

> In the mean time there are thoso who use them now.

Economic illiterates, yes. Ok, there are some who choose to live
off-grid for other reasons. I work with one. Fool (for choosing
to live off-grid), yes. Economic fool, no.

> When the US gets a real oil problem, you can always get one at crisis price.

You're an economic illiterate too. Hasn't the concept of
competition reached that hell-hole yet? ...or are you really
that stupid?

The operative word above is "should". I can't tell you how many times I've repaired rigs with bad RF Amps due to the shut down system not doing it's job. I'm talking H.F., 2 meters, public service radios. Best to test with a good SWR meter or some better equipment like a bird or some other. Do very short key ups til you see where it is initially and take it from there. Just a word of caution.

Lou

I think, other than the pollution, the costs are included in the overall running cost (dead miners, etc. etc.). The pollution is a bit harder to figure, but modern plants are pretty clean. I live close to a big thermal plant and the left-wing newspapers have been running pictures of the stacks (usually with evil lighting) saying that "smoke" is rising blah blah. They've dug up old pictures with all 4 stacks running, and it's usually running at 25%; never more than 50%. Of course it's mostly steam and some CO2- on a clear day you can see nothing in the air discoloring it, just the refraction from the heat and steam trails that rapidly dissipate. The stupid new gov't has been making noises about closing the thermal plants *AND* the nuclear plants- I don't know where they think the power would come from (maybe we can buy it all and export the problem to less "responsible" people). Bleh. Even with conservation measures and some deindustrialization, population is growing at a healthy rate, and so is consumption.

Best regards,
Spehro Pefhany

Does anyone recall seeing an article for constructing a return loss bridge
in RF Design in late 80s or early 90s? I'd like to see if I can get a
scan, I've been bitten by the RLB bug.
tnx

The constant-R load is a requirement for diode-ring mixers, not double-balanced mixers in general. The diode-ring mixer acts like four switches that turn on and off as a function of the LO, RF and IF port voltages. You'd like this to just be as a function of the LO, however.

By it's nature a diode-ring mixer does exactly as good a job of mixing from the IF port to the RF port as it does going in the other direction (this can be handy for transceiver design, by the way). So when you terminate the IF (or any other port) with a non-constant R you get different voltage-current relationships at the image frequency than you do at the intended IF. These oddball voltages or currents (a) affect the mixing, and (b) get dutifully converted into energy that appears back at the RF port to get mixed _again_. Taken to extremes people with very large brains can even terminate a diode-ring mixer make a parametric amplifier from RF to IF.

My understanding is that you don't need a perfect DC to light constant-R termination: you just need to terminate for the expected frequencies out the IF port; primarily the IF and it's image (so RF +/- LO), but to be thorough you should consider the LO's odd harmonics.

Hello Fred,

A diplexer is certainly the Rolls Royce method. Elegant and impressive. But there are others.

You could also provide a buffer amp that has a matching input impedance and the mixer will be happy. One of my favorites is the AD603 if it fits the dynamic range requirements, frequency range and cost limits. That gives you a db-linear gain control of 40dB which often comes in real handy. They don't use Gilbert cells in there but a patented voltage controlled attenuator so there isn't a dynamic range penalty with gain reduction.

Regards, Joerg.

> Last month I went to Palm springs for the Faire, and there was no
> noticeable difference in the numbers of windmills in operation.
==========
Having seen these machines near Palm Springs ,they seem to be rather small
and of an older design.
Modern machines are much bigger (up to 2 MW rated capacity) and more
reliable.
In the Netherlands they are now planning a number of 2MW machines offshore
,approx 8 kms off the coast placed on seabed based stuctures.
Their designers are focussing on minimum maintenance (only once every 3
years) .

To date land based machines produce on average only 16% of their rated
capacity ,due to periods without adequate wind and to technical outage /
maintenance. Yet they seem profitable. In the Netherlands many farmers have
them on their land ,especially
in the northern provinces.

Look here: http://www.amqrp.org/kits/tin_ear/

The vfo in this simple receiver uses the same type of PTO construction. And
the manual includes a schematic.

to
> be much quieter tho.

Yes, it would be because of the lower gain. If you need the AGC associated
with the digital output, you might be able to use a phase detector IC on
that output to detect your 555's frequency. Maybe the phase detector output

would be quiet with no incoming carrier. On the other hand, you may not need any more than what you've already tested. If you're happy with the distance you get using the detector output, don't worry about it.

> I still haven't worked on this yet today, so off I go to work on it some

> back in my lifetime.

They have access to the tech, BUT, they also have to maintain the
distribution system. Since my electricity has been unbundled,
roughly half of my cost per Kwh goes to the distribution co., not the
producer. Ice storms, drunk drivers, blown line fuses all cost money.
As well as the personel and associated benefits packages,
transportation costs of materials, etc. for maintaining the lines.
All this is avoided cost on home solar.

And...
www.solaraccess.com/news/story?storyid=6482

talking about a new discovery:

"A solar cell with the simplest possible physical structure could
achieve 50 percent efficiency or better, far higher than any yet
demonstrated in the laboratory."

It isn't cost effective for most of us yet, but the tipping point
is coming.

I assume you are talking about coal fired plants? They release particles
as well as mercury and radioactivity. There is no clean power.

Hi.
I have spent part of the weekend trying to resonate al old CB XTAL at its fundamental frequency.

The XTAL is labelled 27.125 MHz, with a fundamental of about 9.041 MHz, which falls into 18m HAM band when multiplied by two. I assume 27MHz XTALs are 3rd overtone.

Since the circuitry is/will be digital, the oscillator is one gate of a 74HC14. 470ohm resistor from gate output to the parallel of 1Mohm//XTAL. 10pF and 33pF (from the junkbox) capacitors to ground on each side of the XTAL.

No oscillation (I have no oscilloscope, I use my HF receiver to troubleshoot oscillators at known frequencies).

If I replace the XTAL with a 10.000 MHz rock the oscillation is loud and clear.

I have never built something with an overtone XTAL. I know that I need an output resonating circuit if I want to extract the 3rd harmonic. Do I need the same if I want the fundamental?

Are overtone XTALs "harder" to resonate?

Are those old CB XTALs 3rd overtone?

I assume my 27MHz XTAL works. :-) Thanks in advance for all suggestions,
Paolo IK1ZYW

3158. XTAL oscillator with a XOR gate

Newsgroup: rec.radio.amateur.homebrew

[Slightly off-topic request]

Hi.
As of the other post of mine, another part of my weekend was spent trying to get a XOR gate to oscillate with a XTAL.

I have a working 74HC14 oscillator:
"One gate of a 74HC14. 470ohm resistor from gate output to the parallel of 1Mohm//XTAL. 10pF and 33pF (from the junkbox) capacitors to ground on each side of the XTAL."

Since my project calls for a frequency doubler, which I want to implement with a XOR gate, I wanted to use one XOR gate of a 74HC86 as oscillator. Remaining gates would work as buffer, delay line, digital mixer.

(I have Googled newsgroups and found an interesting discussion about XOR frequency doublers, so I am aware of its limitations.)

So I moved the oscillator circuitry (R; C; R, XTAL; C) from the 74HC14 to the 74HC86, pulling the other input of the XOR gate to "1", so that I would produce an inverter.

Nothing happens. I used a 10.0 MHz XTAL.

I understand that the 74HC14 has Schmitt trigger inputs and that a 74HC86 might have higher propagation delays. Still, is it possible to use a XOR gate as an inverter and oscillator? Do I overlook something?

In the end I recovered the 74HC14 oscillator, but this adds one component to the final circuit I have in mind that wastes energy, space and is underutilized.

Looking forward to your always helpful replies!
Paolo IK1ZYW

Could the crystal be a receive crystal? CB crystals tended to show
the channel number or the frequency of the channel, and so if you simply
looked at the marked frequency, it would not tell you if it's for
transmit or receive. Though the ones I've seen did mark them with
"R" or "T". The point is that if it's a receive crystal, it wouldn't
be 1/3 of 27.125 but 27.125-IF and then divided by three.

I'd say there shouldn't be any problem getting an overtone crystal to
oscillate on the fundamental; if there's any problem it's getting an
overtone crystal to oscillate on its overtone frequency. Of course,
they usually oscillate at a slightly different frequency, so maybe
you need to tune around a bit.

Or maybe the circuit values are wrong for that crystal or frequency.
Or the crystal is indeed dead.

Hamtronics has CW ID modules. Their CWID-2 IDer uses an EPROM and they
will program it for you.
http://www.hamtronics.com/

If you decide to build from scratch, Jameco probably has every
"obsolete" part you would need, but if it is (E)(EE) PROM based, you'd
have to build a programmer as well.

Yup They are 3rd overtone. Try a little series inductance with the
rock, and maybe a few pf of capacitance in parallel. I seem to
remember these being cut for a 25 pf load versus the more common 330
or 32 pf load of fundamental rocks, but the rock may also be defective
(I've seen quite a few) Good luck, Mike.

Yup, they are 3rd. Try a little series inductance or parallel capacitance. A few pf of cap. may do the trick. Basically these were usually cut for 25 pf load versus the usual 32 or so of fundamental rocks. BTW the fundamental will not be at exactly one third of the overtone freq. (I don't remember why) You may very well have a bad xtal too, it happens quite often. Good Luck, Mike

If you don't want to spend an afternoon building a programmer for a PIC, AVR or whatever, be prepared to pay the long dollar. There are few folks these days who would build an IDer from discrete circuits. However, it's a pain in the butt trying to make an IDer programmable for someone who doesn't want to program!

Understand that the "programming" doesn't have to be the barrier you suspect. Taking the PIC as an example, the PIC itself is under $3 depending on the model you choose. It needs 5 volts (a 78L05 and a couple of caps) or a 3 volt battery. If you are nutty about timing accuracy, it needs a crystal, 44 cents at DigiKey, or 98 cents if you want tiny. For an IDer, the only other thing you need is an interface to your audio, probably a transistor and a couple of resistors. If you want to build it up the "traditional" way, you will need a fistful of logic chips and a whole armload of diodes, or an array of DIP switches. Nobody would do that anymore, it's too exepnsive and complicated.

To program a PIC, there are dozens of circuits out there. Probably the one that got most people started is the No Parts PIC programmer from Covington Innovations, because you got to have a pretty lame junk box not to have all the parts you need. Even if you have nothing, you can go down to Radio Shack and get all the parts for under $15, even at their outrageous prices. There are simpler designs, as well. Commercial programmers range from about $20 to over $100. All of the necessary software is available free. Once you invest in the programming capability you now can make not only IDers, but keyers, CW readers, autotuners, synthesizers, and on and on and on.

I used the PIC only as an example. There are folks who would suggest that an AVR, HC908, or whatever is better. None of them change the equation very much. The PIC is one of the simpler parts and has been around a while, so there are hundreds of examples out there for all sorts of applications.

An IDer is a good learning application -- it's hard to think of something simpler. Unless you expect that this will be your last project, it's probably worthwhile to bite the bullet and dive in..

..

Isn't a return-loss bridge electrically exactly the same as the
common-or-garden SWR meter with the meter scale calibrated in something
different from SWR = 1 to infinity?

Same applies to reflection coefficient bridge.

Can't quite tell from your description what your circuit is, but if I recall correctly back when i was doing hardware design a crystal oscillator using logic gates required two gates. I used to use three---two for the oscillator and the third for a buffer.

The two inverters where tied together with a capacitor between them. Then the crystal was placed from the input of the first gate to the output of the second. The output of the second also went to the buffer stage.

!-----------------crystal-----------|
Like this: - gate one---capacitor---gate two---gate three---circuit output

As I recall, there was also a resistor from the input of gate one to ground, and from the output of gate two to ground.

I do not recall the capacitor or resistor values, but when properly built this circuit never failed to oscillate with any crystal within the range of the gates (fundamental mode only).

For all those who asked about the RF design files:

Click on the "Join Now" icon in upper right corner of page and go from
there.
Involves getting MSN passport which is just e-mail address at
hotmail.com
and password of your choice.

There are nearly a hundred files so can't forward them but could any
single
file from list on that page. they are named RFDXXYY.ZIP where XXis month
and
YY is year.

I downloaded them by right clicking on each and chosing "save target
as".
Some reason it insisted on saving it as xxxx.ZIP.zip so I edited out the
..ZIP from each save as so it became xxxx.zip.

Hello again.

Go back to fundamentals. An oscillation occurs when there is positive feedback with a circuit gain of 1. That is, the signal is not inverted at the desired oscillation frequency. Another way to say this is that the phase of the signal at the input and output are the same. If the gain is less than one, the oscillation will die out---inother words it will not oscillate at all. If the gain is greater than one the circuit will 'lock up' at either 0 volts or the power supply voltage.

Most oscilaltors have some type of phase shift device between the input and output to ensure that the phase of the input and oputpuit signal are the same.

Note that in some circuits the feedback and phase shift may not be obvious. A vacuum tube oscillator, for example. Here the feedback is sometimes provided by the capacitance inside the tube.

Everything must be just right for the oscillation to occur and be stable.

With an oscillator built from inverting logic gates, you need two gates so there is no overall phase inversion through the gates. If you are using XOR gates, I would recommend tying one of the input lines on each gate high, That way it will act as an logic inverter.

That was a standard oscillator with TTL. I used a 7400, and 470ohm resistors
from input to output of each gate. No coupling capacitor was needed, though
there was a low value cap in series with the crystal for load capacitance.
(The resistors linearized the gates.)

There were obviously variations on the theme, and your suggestion was
one of them.

And as you say, these tended to oscillate with most crystals. I had one
built up as a module, so I'd have a general purpose oscillator read,
to check crystals or as a signal source.

But, for some reason, when they moved to CMOS oscillators, the norm
became one gate, with a feedback resistor and a pair of capacitors, one
from input to ground, and the other from output to ground.

Parallax have already produced Application Note 8,
which does exactly what you need. You just have to
change one line to have it send the message you want.
Please explain how this is difficult.

Some further comments...

Most oscillators that use a single active device (transistor or tube) are linear analog circuits. You are trying to use a nonlinear (that is, digital) device in an analog application.

The circuit using two inverting gates chasing each other's tail is called a ring oscillator. It can be made to work without a crystal but will be relatively unstable. Most such circuits I have seen using a crystal are in non ciritical applications. I suspect that it will be not too stable (temperature wise) and may not be suitable for use in a radio circuit. Also, you will need to use a good filter becasue the signal will be full of harmonics.

Oh, yes. That rang a bell.

CMOS logic is easier to get to work as an analog device than TTL. At least for the good ol' RCA 4000 series. I am not familiar with the newer 74HC00 series to judge its performance. I would suspect that the 'bias' resistors would have to be carefully chosen and that it would be sensitive to both the crystal frequency and the ambient temperature.

When I was doing circuit desgin everyone most were still using TTL. The 74LS00 series was the hot item at the time.

Just from a logical viewpoint (pun not intended, by the way) I still think he should try using two gates in a ring circuit.

Frankly I'm surprised that you're getting it to work at all with the
74HC14. I'd recommend that you use a 74HCU04 (an _unbuffered_
inverter), or a transistor oscillator with an output tuned to get the
signal strong enough to tickle a CMOS gate.

Yes, you can get each XOR of the 74HC86 to work as an inverting stage by
tying one input high. Then you can get it to act like a linear inverting
amplifier by putting a 1 Meg resistor from output to the other input. Now,
if you have two of these linear inverting amplifiers in cascade, a feedback
path from the second output through a crystal to the first input should
produce oscillation. You may even find that just one of the linear

inverting stages will be sufficient, since there will be a phase shift if you put a 30pf capacitor in series with the crystal. You can control the feedback with the capacitors to ground that you mentioned.

To run a doubler, you need a non-symmetrical square wave or pulse waveform, since a symmetrical square wave has no second harmonic content (only odd harmonics). With vacuum tube amplifiers, this was called Class C operation, since conduction occurred for considerable less than 1/2 the cycle and doubling was easy. Doubling requires about 90 degree conduction (1/4 cycle).

You should get yourself an oscilloscope, if you are a sighted person.

Why is ordering the kit against the point?

It's a manhattan style construction product. All you get is a baggie of
parts, the schematic, and some PCBoard material to work with. A fun and
challenging build no matter how you look at it.

Actually, this probably has more to do with the great public defender they
are likely to get.

> You haven't got the perspective! The sleep on the streets and
> hang out at businesses hoping to be offered work and have
> destroyed whole neighborhoods.

Well, I lived down in Orange County CA for a long time. I must admit that
there are some offensive things going on, but most of the illegals I know
about are not the quintessential Hobos of our modern society. Too much risk
in coming above "the man's" radar. They hang with their extended families,
and out in the farming districts where they get seasonal work. Big
population in Colorado for some reason.

> The problem is spreading and it is
> really bad the nearer you get to the boarder. Farmers along the

> laws.

Beg pardon. These people, except for course for the drug mules that we pay
to bring us our cheap drugs, are the brightest, best, and most ambitious of
a seriously abused population. We might solve 90% of our problems, at the
cost of a bit more expensive lettuce, by making them semi legals and
preventing their abuse.

... (subject. Paying taxes.)
> Not then, nor now! They are a major burden on the state to the
> tune of about $4b a year!

Whew! Is that all? They are responsible for around 12 billion in company
proffits, of which they get around 3 billion, and out of that they pay
around half billion in sales taxes. Actually I expect their employers
collect federal and state tax from their salary, and pay it to themselves. I

think that overall our illegal emegrants likely provide us more benifit than cost, and on top of that they are such an easy target for racial and cultural hatred. Easy to blame our total failure to provide for our own poor by calling them all illegals because some few are, horror of horrors, unable to get legally admitted to our official version of heaven.

BTB, I just made up the numbers for the heck of it. Sounds reasonable to me, so find better ones.

3186. Question about surface mount antennas?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-19 18:37:42 UTC
From: Joe <nuisancewildlife@nospamearthlink.net>
Message-ID: <W%Ugc.2522$e4.2079@newsread2.news.pas.earthlink.net>
Source record: 26672

I am working with RX433 and TX433 modules to create a remote camera control. I previously received some excellent advice on this forum about using a phase locked loop in the receiver section to detect the signal from the transmitter and eliminate most of the noise.

I breadboarded both the receiver and transmitter and gave it a trial run. I am still a little shaky on the PLL, it seems there's maybe a little black magic involved with the design there, but overall the system works. It locks at the proper frequency, but now I don't seem to have as much range as before the PLL. As a 'range booster', I used a piece of 24ga wire about 30cm long on the receiver and about 15cm (almost quarter wave) on the transmitter. both 'antennas' were vertical to the breadboards. That helped to extend the range about another 15 feet or so.

I saw a surface mount antenna advertised in the mouser catalog and I was wondering if anyone has had any experience with these. It is made by Yageo, part number is 4311-121-20043, but there does not seem to be a data sheet on it at the mouser site or at the Yageo site. My concern is that the receiver and transmitter boards will be in the horizontal plane, and I am wondering if a straight up telescoping antenna would output a larger range radiation pattern. If I mount a surface mount antenna to the boards, maybe the pattern will all be radiating upwards? Does anyone know? Also, can someone steer me to a good tutorial or site that discusses radiation patterns of different types of antennas?

TIA,
Joe

Source record: 26673

Using CMOS inverters to build oscillators works best when using "unbuffered" inverters. These can be identified by the letter "U" in the part number, as in "74HCU04".

If you use a buffered part or a part that has Schmitt trigger inputs, then the input-output transfer function becomes very steep (too much gain) and the oscillation becomes hard to control. When this happens, the circuit often oscillates, but at some frequency much higher than the crystal frequency. I've made oscillators out of XOR gates, but if it doesn't come up on the right frequency it can be hard to debug without a scope.

To determine if it's oscillating at all, I suggest measuring the DC current consumption with the feedback removed (crystal out of circuit), and then with the feedback closed (crystal in circuit). When the circuit is oscillating, the current will be markedly higher. Once you know it's oscillating, then you have to determine where it's oscillating. This might be challenging if all you have is a receiver.

Joe

Hi John,

See my question about surface mount antennas posted above (LOL). Maybe I should just leave the PLL out of the circuit and see if I can use just the receiver. The digital pin of the receiver seems to be noisy only when the transmitter it within a few feet of it, once I move it away, the noise goes away. Thanks.

I'm just learning so here's what I know. A RLB is a directional coupler with directivity, isolation and a bridge. Return loss is the reciprocal of the reflection coefficient. A basic RLB has 3 ports, source or input, output or DUT, and coupled or reflected. Connect a piece of coax to the DUT port, a sig gen to source and a meter to reflected. A shorted or unterminated coax will reflect 100% less round trip line loss so the meter will read launch signal less 2 time line loss. If the coax is properly terminated the meter can read anywhere from 30 to 60 dB down, depending on how well terminated in relation to the coax impedance. If you use a tracking generator for the source and a spectrum analyzer on reflected for the meter you can sweep a filter, antenna or whatever you're interested in. Retrun loss is the fraction of power that isn't absorbed by the load. See QST April 1959 pp 24-28 for Warren Bruene's article, "An Inside Picture of Directional Wattmeters."
A retrun loss 1 dB is a VSWR of 17.4, 6db RL is VSWR of 3, 10 dB RL is VSWR of1.93, while a RL of 30 dB is a VSWR of 1.06 and this can be done at low power which is quite difficult with SWR bridges.
Two hams have told me that they've made RLBs that achieved 60 dB. That's my project if I can get the article.

No. The tribes "owned" the land they could defend with their ferocity,
cunning, and a sharp stick or flint ax. They did not farm as individuals but
as extended families, so they had no need to own the land as individuals.
The horse, and the steel blades changed all that quite rapidly in historic
terms, well before the settlers started to sweep across the country.

> be 1/3 of 27.125 but 27.125-IF and then divided by three.

IFs were frequently 455KHz

I have used fundamental crystals on their overtones and overtone
crystals on the fundamental. They are not exactly 1/3 or 1/5 ratio due to
parasitics in the crystal. All crystals have the fund and OT responses, but
the responses are optimized for the intended use - by changing some of the
construction. (I'm talking AT cuts)
Overtone crystals *tend* to be used in the SERIES resonant mode, though
not always. Fundamental crystals tend to be used mostly in the parallel
resonant mode. This will also cause additinal frequency error when using
the marked frequency. The parallel freq is higher than the series (if I
recall correctly)
If I recall, the two gate oscillator is a series resonant oscillator and
the one gate is parallel. I would use a transistor Colpits oscillator
myself. The digital gate oscillators can run the crystal at a higher drive
than it should causing more crystal heating than desired (more drift
w/time).
If you are going to use a OT xtal as a fund., I'd pick a parallel type
osc like the Colpits (I think it has another name when it has a crystal
rather than a coil). I never did like the digital gate oscillators. They
tend to be a *bruit force* oscillator. Because of the Rs of the crystal,
crystals of some frequencies are easier to over drive than others.
Unfortunately, I don't remember which is which.
The fact that your 10mMHz xtal works is a good start. The other one
probably will, but since it was made for the third OT, there may be enough
difference to keep it from oscillating without some circuit change.
If you have no scope, measure the current drain. There may be a change

when the xtal is inserted if it is oscillating. Also, you could try measuring some voltage through a large resistor or choke to see changes when the xtal is inserted.

There are two types of oscillators with gates. Series and parallel.
The former requires no inversion the latter does.

> If you are using XOR
> gates, I would recommend tying one of the input lines on each gate high

He said he was.

I think the biggest issue here is thr Schmidt input. It can't be biased
in the active region.

Well, you know that the coops or companies that built them had to invest heavily and borrow money to finance their construction. What makes you think they can just tear down the old ones before they've paid off their loans, and borrow even more heavily to finance new ones??

The surface mount antenna is likely to be a patch, or microstrip, antenna. When mounted on a horizontal surface, They radiate or receive most strongly straight up, although they do reasonably well at lower angles and have some response at the horizon. Among other applications, they're commonly used as GPS antennas, for receiving signals from satellites. But a vertical antenna would almost certainly do much better in your application.

I don't know of a site or tutorial that gives the kind of basic information you're looking for, but you might find what you need at http://www.cebik.com. Be cautious at other sites, since there's a huge amount of misunderstanding and misinformation about antennas out there, and the ability to make a fancy and professional looking web site has nothing to do with whether the author really understands the subject matter. If you're interested in a little more depth from a reliable source, the _ARRL Antenna Book_ is a good investment.

So the project is done and you want to put it in a box, maybe even paint it...

Well here is a slightly unrelated inquiry, maybe someone here knows to point me in the right direction or give me the proper name for a kind of paint, I call it a crinkle finish, some refer to it as alligator finish.

It is the kind of paint finish you see on Bolex and Arriflex movie cameras, I also see it on military style electronic gear, very resilient, black crinkly finish which also prevents the item from slipping out of your hand.

What is it really called and who would have such stuff??

Usually called "wrinkle finish" or "crinkle finish" paint, I believe.

Antique Electronic Supply carries it in black and grey, at least -
browse http://www.tubesandmore.com/ and search for "paint".

It's apparently available from Krylon as "wrinkle paint", and from
Plasti-kote / Volspar. The Plasti-kote type is being sold as an
automotive spray paint, "Perfect for air cleaners and valve covers".

Do a search on Ebay for "repeater controller". You might try one of Boyds BD-1 repeater controllers, which also make killer ID'ers. B&D Enterprises has a web site that can be found with google.

For about $69 you get a complete controller, that programs as an ID'er and/or repeater controller. You can talk to it with your computer (serial port) and program what ever message you want to transmit. The unit also responds to dtmf commands.

Very Cool!

cheers
skipp

Certainly would be. The other thing about using Schmidt type inputs is
the likelihood of causing longer-term damage to the crystal. They
'prefer' not to be driven to hard and the sharpness of the buffered
gates ain't good for 'em.

Hi Roy,

Thanks, I was reading my Radio Amateur Handbook to try and get some ideas and from the graphic figures they have in there, it did look like a vertical antenna would be better. I wanted to get another opinion though. Also, thanks for the link, I have added it to my favorites. There's a lot of stuff there to read so I can visit the site and learn more as I have time.

Regards,
Joe

Point taken.

But my goal at this point is to build w/ salvaged parts from my mound of junk...

But thanks for all the input. It is much appreciated.

There is still a huge advantage of scale. Without the grid
you'll have to store your own energy, which is certainly not
free. Peak energy usage is not near peak insolation.

Irrelevant. The large producers will have any technology you
will, first and on a much more massive scale.

>

So is the end of the oil reserves. It's been coming twenty years
from now, for about a hundred years. The tipping point will
certainly come, but the large generators will make it there
before your piss-ant house will.

I think the main point is that solar PV is a technology that
does not require massive infrastructure. It's something that
can be done on an individual and distributed basis. The big
power companies really don't have that much advantage over
individuals.

You can find lots of references on the web, too. I think Charles
Wenzel's pages are almost always quite good, and recommend
http://www.wenzel.com/documents/swr.html, but a simple search may well
turn up things that suit your learning style better.

Cheers,
Tom

PS...Hank...sending a scan-to-text of the annual indexes for about
1988-1992, for couplers and whatever else was close to them on those
pages. I suspect it may be Joel Dunsmore's "Simple SMT Bridge Circuit
Mimics Ultar-Broadband Coupler" that you are interested in. I have
that here and can scan it, but you might check out Neil's referenced
site too.

>in the northern provinces.

Those 16 % rated capacity figures seems to be quite low, since usually
20-30 % is quoted for land based windmills near the coast over here.
Of course, if you use a too big generator for a particular place and
wing size, the percentage will go down.

If you use a smaller generator with the same turbine and same
location, the percentage will go up, however, during stronger winds
you can only utilise the amount of power as the generator is rated for
and some of the wind energy is "lost" during stronger winds compared
to a larger generator.

During system design, you can select the percentage by selecting the
generator size. The generator cost compared to the other costs of the
windmill will determine the most economical generator size and thus
also this percentage.

Hi,
thanks to all those who replied and discussed this topic, providing me with a lot of good suggestions.

In the end I might use a BJT/FET oscillator instead, especially if it works with the ex-CB XTAL of my other post. Troubleshooting with a receiver and a DVM is fun, but time consuming and often demotivating.

I dream of an oscilloscope as much as I dream of an HF dipole up on the roof. Hopefully both will come with time, as well as children, a better wage, ... ;-)

73,
Paolo IK1ZYW

I have built a design out the ARRL handbook using a toroid transformer, and SM 100 ohm resistors in parallel to make up the 50 ohm sections. I could get 40 dB return loss to about 50 MHz, when matching a 50 ohm load. This gives an idea of the accuracy of your bridge, ie the higher the return loss in this situation, the better the bridge, assuming an accurate 50 ohm load. I used a spectrum analyser as the detector and the venerable HP8640B for the source.
You can even measure small inductances (I got reasonable accuracy to about 100nH) using a series RLC combination on the end of a length of coax as the unknown load. (ie do it remotely!) R=50, C=is known, L is unknown
At some frequency there is a max return loss. At this freq XL=XC and X(LC)~0, assuming perfect components. Thus the load is 50 ohms. You can work out L knowing C

That also answers most of Reg's question about the difference between an RLB and an SWR bridge.

As Reg has often pointed out, the so-called "SWR bridge" is actually a reflection coefficient meter and it generally includes its own RF voltmeter.

An RLB generally doesn't, but has an RF output port for the reflected signal. That port is intended to be connected to a sensitive external RF power detector - such as Richard's spectrum analyser - which can accurately measure reflected signals down to -40dB... or even lower if you consider such readings meaningful.

Another difference from the normal SWR bridge is that an RLB is always a true bridge, with separate 'unknown' and 'reference' ports.

Normally your standard Zo load lives on the reference port, but if you remove it, you can then use the RLB to compare *any* two impedances that are intended to be the same (for example the two halves of a stacked yagi array). You can see how alike the two impedances are, without actually having to measure the value of either one... a very handy feature.

Sorry Anthony, but I think this is quite wrong. Solar PV requires a very large infrastructure to build, and a substantial infrastructure to maintain. The cells may last 100 years, but the inverters, storage batteries and the like, are more typically 5-10 years. And, many of us do not live where sunlight is all that reliable. The more unreliable, the larger and more expensive the system that is required, and the more severe compromises have to be made to keep the night light on. The PV systems, to obtain maximum practical usage for the civilization as a whole, need to be installed in mass in the desert regions down in the temperate zones in the us, Texas and like that. This puts the big power companies in the cat bird seat, still. But it is that, or pay 3-4 times as much for the same electricity from a system that gives you constant headaches maintaining yourself, and one that may actually consume more power to build and install than it can produce in it's life, because we insist on living where we want instead of where solar power pays off.

Sure they do. While you are dicking around with solar cells the big
power companies will build a solar-powered steam plant with *huge*
servo'd mirrors. I put pencil-to-paper once upon a time... you can do
marvelously if you've got the acreage.

Your _doomsday_ assertion that oil reserves are ending is totally ridiculous. There are a zillion gallons of oil locked up in shale in North America, just waiting for an economical way to extract them. Problem is, they cost too much to extract, so that's not practical _at_this_time_. But if the price of petroleum continues to go up, then finally someday the point will come where the cost to extract it *is* competitive. Then it will get included in reserves.

Another possibility is that if the cost of petroleum continues to rise, the cost of alternative energy sources may become more competitive, and will replace petroleum. Alcohol from corn is one that comes to mind.

Maybe if the cost of gas goes up another buck or so, I'll be able to drive down the street without having to fight so much traffic. All those gas guzzling vehicles will drive their owners to the poorhouse and they'll stay off the roads. ;-)

I don't know about that. Solar PV can be used in any size from digital watches to powering hotels. Big power companies have to buy the same parts as individuals and would mostly pay similar prices. The large infrastructure to build and maintain them is called "the rest of civilization" for the most part and is accessible for an individual as it is for a big power company.

Oddly enough, many people do live where the sunlight is fairly reliable and a PV system can be small enough to be practical for an individual. The civilization as a whole is just a collection of individuals when you look at it closely enough.

> power pays off.

Grid tied systems need close to zero maintenance so I hardly see that as giving constant headaches. Even with a battery system, I've heard about some that only require a checkup every six months or so. Lastly, while PV may be more expensive than grid power, I don't think that a big power company can build solar PV all that much cheaper than anyone else.

Thank you Keith, as for the drugs I cannot help you there.
But this morning it occured to me that it is purely academic,
kill Iraqies, for the oil, sell the oil, buy food from that
money and eat it -versus- kill and eat Iraqies directly.
So cannibals applies.
Since you did not object to that, I take it you vote for impeachment
of the Bush clan too?

Arizona Public Service has a similar operating facility west of
Phoenix that, for some reason, is kept very hush-hush. It was in the
papers a few years ago, then no more mention.

The efficiency of such a system FAR exceeds what will EVER be attained
with photo cells.

So, first you have to build and support a huge civilization, not stand alone as an individual. Big point that. The power company would buy in really large blocks, install in a single area without pre-existing structures in the way. I would be surprised if their PV installed cost were (assuming they are in this for profit not subsidies) any more than a third what the individual must suffer. Of course a skilled do it yourselfer with time to hunt up bargains might do a lot better, but this has to apply to the whole people, not just the few.

...
> Oddly enough, many people do live where the sunlight is fairly reliable

I am not saying that an individual cannot spend an arm and a leg, buy a system that is three times the size of an optimized well sited system, overwhelm everything with massive and expensive battery storage, and be perfectly happy with running out of power in the middle of microwaving his hot dogs, but you gotta recognize that overall this process needs to be made as inexpensive as possible or it will make most of us a lot poorer. I am concerned that you are seeing that a PV system can be built, but not what the trade offs of this system imply to our lives. I believe that when PV electricity becomes cheaper than coal/natural gas/uranium, (if it can), then most of us will be buying most of our electricity from huge PV arrays in the southern deserts, not from a little farm outside our town. There will be few who will "roll their own", and some small town back up plants for summer peaks and such, but the bulk power has to be the cheap power and that has to be large and in the right place to make solar power.

...
> Grid tied systems need close to zero maintenance so I hardly see that as

Grid tie is great for a small system or two. If we get more than 20% from such systems, the grid has to be redesigned to be a storage system of sorts. I overstated what I think is the actual level of difficulty to get you to think about the demand you are making on the ordinary citizen to maintain his private power system. Every few years he has something break down, and he knows nothing about it. The maintenance costs eat his profit for dinner. A tree branch, an ice storm, a battery failure, a lightening bolt, and his system is disconnected from the grid so he can turn his lights on, and we are back to the centralized distributions system. Your last point, that you think a big company can not build PV much cheaper than Joe, and the general implication that the cost to Joe of electricity from his local PV system is competitive with ConEd from the Mohave Desert by way of the grid, needs a lot more quantification I think. As I recall there is around a 3 to 1 difference in the average solar insolation between Seattle and Phoenix, for example. It is pretty hard to make up for that kind of a cost differential, but on top of that you have to add even more storage someplace for all that electricity, since the winter insolation up here is really crappy for months on end. That is one heck of a lot of storage, and to do it locally is generally from hard to impossible. (In Seattle we might be able to find a nearby mountain valley we could turn into a lake for hydrostorage, but a lot of locations are a long ways from any possible storage site). .

Get something working with a good crystal first.

A Google search (Colpitts Crystal oscillator circuits) turned up lots of gate oscillators. This has the type of transistor oscillators I am used to using:

http://hem.passagen.se/communication/txo.html

There are many other references at:
http://users.telenet.be/educypedia/electronics/analogosciltypes.htm

I don't like this circuit:
http://www.electronics-tutorials.com/oscillators/crystal-oscillators.htm

It's pretty close to obsolete, you'd be well served to buy the brand new Experimental Methods in RFDesign. However, I have always maintained 2 copies, one for the shop and one for the reading room you know. I just was the recipient of gifts from two very kind fellow hams, Donnie Lee and John Larkin, and in an attempt to repay their thoughtfulness would happily mail you one of my two copies of SSD if you'll send me your snail mail address.

I dunn-o. I had great success with this cricuit. It's used in all the older Motorola channel elements. Just about any rock will fly at the fundamental unless its really bad. You can play with the ratio of the two feedback caps (Base-to-emitter and emitter-to-ground) Base-to-emitter cap decrease to get more feedback. I even modeled one of these on P-Spice. Really neat to see it oscillate.

Just in case you might not know. . .

There's a newer book that contains a lot of the same information, plus more, and a CD with some very useful programs and data. It's _Experimental Methods in RF Design_, by Hayward, Campbell, and Larkin, available from the ARRL and many bookstores.

Unless you want _Solid State Design_ for a collection, you might consider the newer book.

Depending on how small and low power this has to be, you might even go the large route and buy a $15-20 used 386 or 486 computer with sound card, that way you could have a voice id, interfacing to the radio isn't too difficult. Something like the psk or mntty interface to trigger the radios ptt, and a simple program to do the timing and send out the audio.

I won't take that without a bit of study. The solar cells take a scads of energy to build, but once built run for a very long time without much maintenance. The thermal system is mechanically more complex, requires a lot more maintenance, is more sensitive to wind loading, and of course you are running pretty cool so the thermal efficiency is not all that great. I would think the solar trough is more like 20% and probably much closer to PV than you allude. The very large focusing arrays can run a lot hotter, and may then give you a bit better efficiency, but you are still not likely to make much over 40% and even at that, if you add in the higher rates of "dead" space that the big focusing arrays use, you may find the total percentage of energy recovered per square mile to be under 20%. The cost per KWH recovered is, I think, the killer here, and the increased maintenance adds a lot to this cost for the thermal array.

Hi all,
I seem to have missed something here.
The OP wanted a CW ID Keyer and we've all came up with
various options. Some people are choosing products at over
$50 and the most recent one suggested a PC. Everyone has
had their reasons for these.

A problem I have here is the OP hasn't really given us a fair
chance of replying well, due to lack of information/feedback.

If the OP basically wanted a CW ID Keyer as suggested, I really
fail to see why a simple K1EL keyer for aroud $10 can be beat.
A K10 is programmed by CW, it has a beacon mode and lot's of
potentially useful features.

Please OP, tell us what you really want as this thread is beginning
to frustrate me due to all of the options, wide price range and
huge variations in complexity.

I understand we're all trying to help but the thread is getting
crazy on price and complexity for an oh-so-simple problem!

Rv!

David,

if you are lucky you will find a copy at a radio rally. I bought a copy
for 50p at the Swansea Radio Rally. I also saw a copy at the Yeovil QRP Radio
Rally but at a cost of ï¿½5. I've seen copies at other rallies too.

I've nearly read the book from cover to cover and it is indeed an excellent
reference. I have learned much.

The point is not whether or not they can be used, but whether or not
they can be used economically and profitably.

Oh, if that was the point then it's already been decided. Right now,
solar PV is not economical or profitable except in niche applications
not connected to the grid. Tomorrow... who knows? It does seem to be
getting cheaper all the time.

This, of course, has nothing to do with the question of "Is the
profitable use of solar PV limited to big mega-corporations?"

If we go back a couple of articles in this thread...

Some technologies simply can not be affordably implemented on a small
homeowner scale and for them to be used you need a big company or co-op.
Solar PV is not in that category. The example of a solar powered radio
shows this. It does not require huge resources to build, buy or

maintain. The basic idea is that when it comes to solar PV installations there really isn't much advantage of scale. A huge installation will cost only slightly less per watt as a smaller one.

Actually, the OP said IDer, not ID Keyer. Since the application was in the broadcast band, it seemed odd to me that he wanted an IDer, but clearly, I don't understand his application. I sort of wondered whether the COR was part of the problem, too, but he never revealed that much about his app. He seemed relatively happy with the Hamtronics choice, kinda pricey I thought, but they program it. That, apparently, is worth something to the OP. I suspect he may not know Morse so the K1EL keyer wouldn't be much use. In any case, he seemed to totally ignore the keyer suggestions, liked the high priced spread, and indicated he wouldn't mind rolling his own if he had the time.

I thought the 386 was a great suggestion in the true ham tradition. We're always looking for small, sexy solutions, when an old boat anchor could be pressed into service practically free. Well, except for the time, and that, apparently, is an issue for the original poster.

3254. soldering with a lighter

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-21 01:38:46 UTC
From: dave d <no@sbcglobal.net>
Message-ID: <Ggkhc.19493$854.14711@newssvr22.news.prodigy.com>
Source record: 26641

Many of you probably figured this out already, but it was a revelation to me. I recently had to do a quick field repair out of my car. I had a voltage inverter and a small iron, but it didn't do very well. That iron has always been wimpy, and between possibly low voltage and cold ambient temperature it didn't work out. I then thought about how much my new Scripto wind resistant long-necked lighter (the kind you use to light a grill) looked like a small blow torch. It really puts out a good strong, tight flame. It wasn't as precise as I would have liked, but it was plenty hot and got the job done with only a few charred edges on the connector that I was repairing. I tinned the free wire away from everything else, left a small mouton blob hanging, quickly got it close to the multi-pin connector where it had to go, and hit the connector very quickly with the flame. It makes me wonder if a decent-quality little torch wouldn't be good for more soldering jobs, especially on thick parts.

See above links for various possibilities, sorry I can't help you. However, being a 'film professsional', by virture of my job, I've also seen these cameras 'up close'. What I was wondering was: is this truly 'paint' on those Arri's or more like a custom colored & baked on finish. The finishes are almost bulletproof / scratchproof and talk about resilient. If those cameras are indeed 'painted' - it's amazing because of it's durability.

Thanks for a good question

These are Swiss and German cameras, after all. They don't fool around.
Commercial wrinkle finish required a few steps to complete, it wasn't simply
sprayed on. Like all good paint jobs, it was baked, which hardens it. I once
saw a 1969 GTO done in black wrinkle. Saved having to wax it, I guess.

Source record: 26498

This is a bit, long but bear with me it is hombrew releated.

I'm one of the principals in a company called NetBurner.
We build Network enabled CPU modules etc...

The company has some core capabilities,
PCB design, Fab, SMT Assembly (BGA, 0402's) ,
Order processing, order fufilment UPS shipping etc...

As a ham and an engineer that likes to build things
I'm frustrated with some of todays finer pitch SMT technology.

I've often contemplated using the business to come out with a line of
"Hobby" oriented PCB's
Things like an ADI high end DDS
Some of the cool direct conversion mixer IC's ...
Simple switching power supplies...
Small uP boards (AVR etc...)
RS-232 level shifters....
MOSFET full bridge motor drive.
ADC's
DAC's
Audio amp chips...

and so on....

I'm not looking to make any $ on the hobby product line, but I'm not
looking to loose any $ either.

As a first pass we would build things that I would find fun to play
with.

The boards would be fully assembled, with a minimal implmentation of
what ever function they are supposed to do. Nothing fancy, nothing
extra just modules hobbiests can play with.
Support would be limited to Schematics and E-Mail.

Since almost all sales would be 1's and 2's cost would be about 4X
the 100pc component cost.

Would one sell any of this stuff?

What sort of modules would you personally buy?

Paul (KL7JG)

I remember I have read about technology for soldering wires: Remove the insulation and twist them together. Wrap the twisted wires with thin solder (i.e. "wire" containing the alloy and flux). Pack all this into aluminum foil tightly. Heat with a gas lighter for several seconds. The aluminum foil helps to distribute heat, prevents the solder alloy from dripping, the copper from oxidation and the flux and the wire insulation from burning. It can be removed after the connection cools or it may be left where it is.

If you're out on the road, then whatever works is good.

Back home, a better use for a flame is as background heat for the
regular small soldering iron. The background heat provides most of the
temperature increase, but not enough to melt any solder. Then the small
iron *can* melt the solder, exactly where you want it.

This technique lets you do fine-detail soldering, even on large lumps of
metal.

Other background heat sources include an electric hot-air gun, a gas
torch (at a distance, never close-up) or sometimes the cooker hob.

This is definitely my preferred method for soldering PL-259s, even
outdoors in the cold: a quick blast from the hot-air gun onto the plug
body, and then the regular workbench iron works fine.

(Yes, I *do* have a traditional monster soldering iron, I *have* used it
and of course it *does* work. But not as well. This way works so much
better, I've forgotten where the monster iron is...)

Paul

I think the NJQRP DDS Daughtercard is a good model for something that would sell. Indeed, NJQRP has had to take a break on making them because the volunteers who actually kit them are totally fried from assembling literally thousands of the things.

NJQRP and AmQRP have had remarkable success with their kits lately, not just the daughtercard. The PIC-EL had to be stopped after only a couple of months, again, because they neede a break more than anything else. Ditto with some others. I'm not sure what the magic is, but the daughtercard is a component in a number of other kits, as well as providing a simple module to solve a hard problem for folks homebrewing their own stuff. Of course, they have the unfair advantage of free labor, but on the flip side, they don't have the access to volume discounts that someone who was making a lot of other stuff might have.

With high quality circuit boards, I think the TSSOPs are within reach of most amateurs. Most of us, however, can't make circuit boards with that sort of feature size. The appearance of even more frustrating packages like BGAs is worrisome, though.

One of the challenges, of course, is that with these newer, more complex circuits, amateurs don't become comfortable with them until well into the product lifecycle. By the time the amateur community latches on to a part, it is already obsolete. This can lead to a pretty short life for some of these things. Some kits like the Small Wonder Labs DSW had to be pulled because the parts went out of availability almost before they appeared.

A potential way around this might be to package functionally complete modules that folks could use without really having to get to know the innards. This eliminates things like the synthesizers that really need microcontrollers to operate, thus requiring builders to get familiar with them, but perhaps something like a mixer, IF strip, etc. might work.

A lot of the builders these days are QRPers, and they are always looking for reducing size. I would think something like the FAR Circuits 9850 board, but entirely surface mount, might be a hit. You would need to provide some sort of ICSP port for this to play, however. And the 9850 has to be well along in its lifecycle. Personally, I would like to see some sort of quadrature DDS along with a Tayloe mixer pair.

Another angle you might pursue is using AmQRP to market the things. AmQRP is having trouble keeping up with the demand for their stuff. They really do seem to have figured out what sells and what the price point is. What they haven't figured out is how to assemble the kits in the sorts of volume

they are seeing. I don't know how comfortable they would be with that sort
of model, but given your production capability, and their access to the
market, it seems to make sense.

I have built a few LC oscillators (VFOs) using a single gate of a
74HC04. Yes I know the 'HCU-4 should give less trouble, but I didn't
have any at the time. For an example, see

http://www.arsqrp.com/ars/images/backissue_images/2002_images/0602_images/ve3sma_images/Vfo1.gif

It should be possible to insert a crystal somewhere in the feedback
path to get a single-inverter crystal oscillator, though I have not
tried it. The key is that the tuned circuit is used to provide an
extra 180 degree phase shift.

In fact I notice, now I am starting to completely wake up this
morning, in my link if you remove all the tuning components and
buffers, short the 330pF cap, and replace the inductor with a crystal
it becomes a standard crystal oscillator circuit used with the 'HCU04.
Seems to me it should work with the 'HC86 but there is always the
possibility of spurious oscillations with such buffered gates.

A very well-reasoned reply. AmQRP has been the victim of its own success.
Based on the number of sales, I'm surprised no commercial vendor has offered
to PIC up the job. The prices would go up, of course, but there is still a
large demand, and many QRPers (not this one!) seem to have deep pockets.
Analog has been pretty well beaten to death in the QRP domain, and there
will be a growing market for products that are closer to the
state-of-the-art.

More and more new rigs are coming with VHF/UHF weak-signal capability as
standard. While not directly DDS-related, I think there may be a nascent
market in inexpensive narrow-band VHF/UHF transverters and transceivers,
too. What's available now is excellent, but priced accordingly. We have to
get more activity going on those bands or we're going to lose them.

No, my favorite one was the "Blood for Oil" screamers.
Since we aren't getting the oil and our prices are now on the rise the
same group is now claiming that it was all a plot to raise oil prices so
"they" could reap huge profits. See how no matter what happens there is
still something to bitch about and it is always "their" fault. Sort of
like the Y2K hysteria.

I like it that the Dutch solar car went cross Australia in 3 days or so
with an average of over 100 km/h last year.
Now here is a very sensible application in a suitable 'solar' climate.
Those photocells were the same as used by the European Space Agency.
I would love to have a few square meters of those to play with.

Well, Jim, my favorite is the fact the oil companies are reaping super profits and able to claim it has something to do with a minor adjustment in the price of foreign oil. Certainly nothing they are doing to adjust their company profits. Really! Ignore the man behind the curtain. Yeah, sure!

There were several variants of this chart recorder, 680,681,682,683. The one I remember used Esterbrook pen cartridges, HP part numbers 1530-0095 (blue), 1530-0703 (red), 1530-0704 (green), 1530-0984 (purple), and 1530-0905 (black). The cartridge was mounted on the inside back wall of cabinet, and attached to the pen stylus with a capillary tube about 8" long. You might still be able to obtain the cartridges from an office supply store. Manuals are available at http://www.manualsplus.com

I particularly recall one incident where a technician was trying to clear a clogged capillary tube. He disconnected the tube at the stylus end and fitted a 10CC hypodermic syringe to the loose end. He then shoved the plunger with great gusto and the next sound I heard was a loud "POP!!!". The cartridge exploded, covering his face and shirt with red ink dots.

Nothing authoritive. Just old news editorials criticizing Ike, but not specific enough to say exactly what was done and when. It wasn't much of an issue then. Just needed to be done.

3277. Re: homebrew specialty paint finish

Newsgroup: rec.radio.amateur.homebrew

Source record: 26514

So here is what happenend, following some of the leads from here I got myself a can of wrinkle paint through a local automotive supplier.

They want three heavy coats spaced ten minutes apart and then leave it alone for 24h.

The wrinkle develops after 2 or so hours if you did everything right, mostly that means heavy even coats.

I tested the stuff on an angled piece with corners and crevices and there it is difficult to control the thickness and the results vary also. A flat portion seems easier but you still need to control the thickness otherwise you will end up with areas which don't wrinkle.

For my purpose, rejuvenating the face plate of a military type electronic device I think I will be fine, but I can see that there is definetly a learning curve before I spray paint my Bolex movie camera here in the kitchen...

Regarding 'series' and 'parallel' modes, ALL crystals actually resonate
in a series mode.

The simplistic equivalent circuit of a crystal is a series L-C tuned
circuit with a capacitor across the whole thing. The series C (call it
C1) is relatively very small (compared with the parallel C, C2) and the
L is very large (ie the L/C1 ratio is large). The parallel C2 largely
consists of the physical capacitance caused by the plating on each side
of the actual crystal. In some circuits the value of C2 is deliberately
increased by adding actual parallel capacitance (see later).

Looking at the equivalent circuit, you will see that the series C1, the
parallel C2 and the inductance are all in a loop, ie the three form
another series-tuned circuit. As C1 and C2 are in series, the
straight-through 'series' resonance of L and C1 must be at al lower
frequency than the 'parallel' resonance of L + C1 + C2 (although the two
resonances are always very close together).

In the 'normal' series-resonance mode (L with C1), an RF current is
simply fed through the crystal. This will be the case when it is
connected between the pins of an IC and there are no other 'tuning'
elements. Adding parallel C should have no effect on the
series-resonance, but it does bring the 'series' and 'parallel'
resonances closer together. This tends to force the oscillation
frequency lower. The 'parallel' mode tends to be more applicable where
impedances are higher (eg in a Colpitts circuit).

As C2 is much greater than C1, the oscillation frequency does not change
much if C2 is varied. However, it does change. Most crystals intended to
operate in this 'parallel' mode specify their frequency with a 30pF
shunt capacitor. Such crystals are usually used at the lower frequencies
(up to a few MHz). At the higher frequencies, the 'series' mode is
almost always used.

As C1 is very small, in the 'series' mode (L and C1) adding capacity in
series with the crystal has very little effect on the frequency unless
the extra capacitor is itself very small (and this tends to kill the
oscillation).

Finally, 'overtone' crystals should always be usable on the lower
overtones (essentially the odd harmonic frequencies of the fundamental),
and may (even if some TLC is required) operate on some of the higher
overtones.

I think I have this right!
Cheers,
Ian.

3279. Toroid ID question...

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-21 22:55:20 UTC
From: J Shrum <shrumj@madisontelco.com>
Message-ID: <D-idnbluoKhTZhvd4p2dnA@shawneelink.net>
Source record: 26516

Greetings,

Recently I bought a grab bag of mixed toroids from www.allelectronics.com .
I bought some T-37's and T-50's. The problem is... they're not color coded,
and not identified by mix. So I have mystery toroids T-37-?? and T-50-??...

The question is, is there a way to come up w/ a rough estimate of the mix
value? I wound some test coils and come up w/ these figures:

T-50 15turns 30awg = ~150uH
T-37 9turns 30awg = ~180uH

Perhaps there is a chart or something similar somewhere that I have
overlooked that will give me an idea.

Thanks for all assistance.

Jim Shrum - KC9FFX

Look at the tables in the ARRL Handbook, in 2003 it was in Chapter 24, for tables with the info you need to calculate the inductance on a given core with a certain number of windings. You need to solve for AL obviously since you want to find your core.

The equation goes;

Turns = 100SQR(uH/Al) where Al is the inductance in uH per 100 turns)

and

15 = 100SQR(150/Al)

and (0.15)^2 = 150/Al

and

150/0.0225 = Al = 6666.

You have ferrite not powdered iron.

For Ferrite, it's just the conversion

Turns = 1000SQR (mH/Al) where Al = mH/1000 turns

15 = 1000SQR(.15/Al)

and
0.15/0.00225 =66 which looks like, (for T50 core) material 61

And the T37 core, at 2200, looks like 75 material, look out for it's bulk resistivity which is pretty low.

Al = 150uH * square(1/15) = 667

> T-37 9turns 30awg = ~180uH

Al = 180uH * square(1/9) = 2200

See if these Al values look realistic. Even if not, this is the value of inductance of one turn for the core which some manufacturers used as Al many years ago when I worked with the devices. The inductance ratio varies as the square of the turns ratio.

Start at http://www.amidoncorp.com/aai_productselection.htm

Follow the "Iron Powder Cores" and "Ferrite cores" links.

The formulas, and the specific inductance index A(L) values for
various toroid formulas, are on those pages.

It's important to note that the A(L) values are stated in different
units for the two toroid types. For iron-powder cores, it's given as
"microhenries for 100 turns", while for ferrite cores it's
"millihenries for 1000 turns".

But not always! Many cb sets used an if frequency of 1600khz plus or
minus a few 100khz. I have some old Lafayette if cans at 1650khz that
came out of an old cb set. Some also used double conversion with a
first if anywhere from 1.5mhz to 13mhz and a down conversion to 455khz.
So that receive rock could be anywhere in frequency.

If they are not color coded then I guess they aren't Amidon toroids,
at least all the Amidon toroids I have seen were color coded, Amidon
does have all the specifications for all their toroids posted on their website
though:
http://www.amidoncorp.com/aai_productselection.htm

>The question is, is there a way to come up w/ a rough estimate of the mix

If you are running Windows, you can use this program to do
quick inductance calculations for many different toroids types:
http://www.qsl.net/dl5swb/minirk_e.htm , and to get specs on
different toroid types. A real time saver for calculating the inductance values
and it also shows the Inductance Index for each toroid and the frequency
bandwidth for that composition type, which might help you to get a better
idea of the composition type of your toroids. I think it will still be hard to determine
the composition types for certain, although the different composition types do have
different Inductance Index values for the same size toroid.

<< I got
myself a can of wrinkle paint through a local automotive supplier.

They want three heavy coats spaced ten minutes apart and then leave it alone
for 24h. >>

Uwe-

It sounds like you're on the right track now.

I played with wrinkle finish paint as a teenager, fixing up several old
pot-metal microphone cases. There are probably more options today than there
were then. It may have been Krylon that I used, but I don't recall.

One thing I remember, is that you can get non-wrinkle paints to wrinkle by
applying a second coat before the first has dried completely. That is
essentially what your instructions do, except your automotive paint should be
optimized for wrinkling.

Three coats may produce a gorgeous wrinkle finish, but I wonder if it might be
delicate to handle. You might run tests to see if two coats will wrinkle
sufficiently and not be as easily damaged by rough handling.

Another thing to try while you are experimenting, is to wrinkle-paint a sample
item and then bake it. You don't want to scorch the paint, just let it cook
for 30 minutes or an hour at 200 or 250 degrees F, and let it cool. See if
that toughens the wrinkled surface so it will withstand some abuse. (If
someone knows about baked-on paint, they may give you better advice on time and
temperature.)

The 9850 is still a listed part, but the latter ones in the 9850 series

with the built in clock multiplier (almost a pin for pin replacement)
are a better bet. The 9950 series are current state of the art and with
their 400mhz clocks and 14bit d/a's are cleaner too.
I'd like to see a kit or circuit board based on the 9954. BTW you can
get these as samples for just a little begging. Analog Devices likes to
send samples to hams.

> So that receive rock could be anywhere in frequency.

Which is why I didn't specify the IF. I thought the original poster
might be listening on 1/3 the marked frequency, but if it's a receive
crystal it wouldn't be there. And while assuming an offset of 455KHz
might be a good 1st guess, one could listen there on a receiver and
still not find something. It still doesn't answer the question of whether
the crystal is oscillating if you don't hear anything at the expected
frequency, because it might be on some other frequency.

Years ago, when I would fiddle with oscillators, I'd put the SP-600 that
I had at the time on it's highest band, 30 to 54MHz. Then with the oscillator
on, I'd spin that knob. A few good spins got it across the dial. I'd find
a spot where there was a carrier, and then do some fine tuning. Then
I'd shift down in frequency, looking for a submultiple of that frequency,
until I found the actual operating frequency.

A digitally tuned receiver let's you find the expected frequency much faster, but you still need to tune around if the crystal isn't at the expected frequency.

"Michael St. Angelo" (mstangelo@comcast.net) writes:
> Dave,
>
> I great book. Check hamfests. I got a copy for $1.
>
> Mike N2MS
>
>
I haven't seen the new book, but I can't quite imagine that buying it
would negate the old one completely. I have a selection of handbooks
going back 40 years, and even the incremental changes between years when
I did buy them every year (much of the seventies) is enough for me
to keep them. I don't think much of the 1979 edition, but it has
the chapter on NBVM, "Narrow Band Voice Modulation", that made such
a splash that year and then completely faded out, with no later mention
of it.

I love Solid State Design, there's a very good mix of construction to
theory, and obviously it did cover territory that the Handbook didn't
at the time. My copy, bought when it first came out, has stood up
better than some books I have from the same time period, but I'd be
disappointed if it fell apart and I couldn't get a replacement.

Old books often do have value, even if later books are more up to
date. The early ARRL SSB manuals, and the CQ SSB Handbook for tht
matter, tend to be more in depth about the basics than material written
years later, because by then "everyone knows all the details".

And sometimes even the historical perspective is of value. If a low
frequency crystal and a string of multipliers was the norm for years,
as seen in the ARRL VHF Manual (which hasn't been published in at least
thirty years), then sometimes it still can be the proper choice. But
if people don't see those "historical documents" they may be puzzling over
how to do something except with the latest whizband schemes.

Besides, the old books are what I grew up with. Some of them were new
at the time, some of them were bought used and were already old at
the time. But I read them, and reread them, and if nothing else,
they are a remder of that past. When I got interested in them, I
got rid of my comic books and my Tom Corbette and Tom Swift books,
and years later I regretted not being able to reread them. I did
not make the mistake with radio and electronic books.

There are lots of web resources. Here's one:

http://www.amidoncorp.com/ace_iptcforrf.htm

And another: http://www.bytemark.com/

You can search for Amidon or Bytemark or Fair-Rite or Ferronics, and
also just search for 'powdered iron toroid' or 'ferrite toroid' and
find lots of things. Those links will take you more-or-less directly
to Al values for a wide range of cores. Just remember that inductance
goes as the square of the number of turns, so if Al is uH/100 turns,
the inductance will be Al*(your_turns/100)^2.

Cheers,
Tom

There's some history behind NBVM. I guess it must have been in 1978, but whenever, then-ARRL General Manager Dick Baldwin, W1RU, wrote an editorial for QST with the theme of "We need a technical breakthrough," like the ones hams were famous for in the past. Weeks later, NBVM popped up out of the noise, and Baldwin ordered an article about it published in QST, with a cover photo to match. AFAIK, no one else at Hq had ever heard of NBVM or the inventors, and I wouldn't say the idea caught fire among the staff. But there it was. The hardware was commercially produced by a publicly-held company, but I never saw evidence that anyone officially connected with ARRL owned any. If they did, it was their loss.

At that time, ARRL, as Headquarters society of the IARU, was preparing for a World Administrative Radio Conference (WARC). This was one of the big WARCs and there was some concern that we would lose HF spectrum. The official story, of course, is that we gained the WARC bands, but in terms of net spectrum it was a loss, due to incursions on the microwave bands. My recollection is that we took a major whack on 13 cm, and also on several other uw bands.

So that's the backscatter on NBVM.

I have successfully made a circuit using a single gate of the 74HC86 similar to you describe. I used 1K from the gate output to the 10MHz crystal. 12p capacitor on either side of the crystal to ground. It works very nicely! See the circuit diagram here:
http://www.hanssummers.com/radio/qrss/qrv/mod2/index.htm .

You could build something with an EEPROM and some counters. See my 30m beacon project http://www.hanssummers.com/radio/qrss/index.htm . There's no microcontroller in sight. But it's replaced by, err..., quite a number of TTL etc. If you didn't want all the features and you didn't want to be able to reprogram it frequently, you could come up with considerable simplifications.

Message-ID: <TF_hc.74135$oj6.38244@bignews6.bellsouth.net>
Source record: 26550

I have about a half dozen 3.333mhz and 5.0688 crystals. Each group is with in 100hz of the same frequency when put into a simple oscillator. I also have a few 11.0592 crystals that are almost as close (probably should get a few more of these). The 5.0688 and 11.0592 are in HC49/U cans, the 3.333 are in a somewhat larger sized can.

Wonder if any of these groups would make a good ladder filter for a receiver IF strip? I would guess the 3.333 ones would be better for CW, the 11.0592 for ssb, and the 5.0688 might be a compromise either way?

Use program TOROID from website below.

Enter into the program the data you already have, core dimensions and inductance, and the remaining information such as core permeability, the number of turns for other inductances, will be computed.

Program avoids guessing who is the manufacturer. Who needs to know if you have already grab-bagged the items.

From inductance/number-of-turns data you can guess the type of material, ferrite or iron powder, if you are interested.

Download program TOROID in a few seconds and run immediately.

March your way into the weekend!

Join Nader supporters in DC, April 24-25,
as they rally for justice and equal rights

Washington, DC:

Saturday, April 24th, IMF/World Bank Protest - meet at 11am, 15th & H St, NW.

Sunday, April 25th, March for Women's Lives - meet at 9:30am, Smithsonian Metro Stop.

If you arrive late, ask a volunteer to point you towards the Ralph Nader group.

See you there!

Nader: Oil the Source of Two of Earth's Major Problems:
Wars for Oil and Climate Change

Protect the Environment and the People of Our Planet by Ending Our Addiction to Oil

Washington, DC: On Earth Day 2004, Independent presidential candidate
Ralph Nader highlighted as two priorities: ending the Iraqi occupation
and facing up to the immediate crisis of global climate change. "Future
geopolitical crises involving oil resources and environmental problems
will be diminished by finding alternatives to fossil fuels," said Nader.

Nader linked the two issues on Earth Day because he sees them as
symptomatic of the corporate oil-based, planet destructive behavior of
the Bush Administration. Nader has called for the United States to
withdraw from Iraq - including military, private military contractors,
oil industry and other corporations. Nader noted: "The war in Iraq is
unleashing widening cycles of violence. The potential for escalation of
violence increases every day the US military remains in Iraq. The way to
reverse the spiral of violence is for the United States to go back home.
The US presence serves as a magnet for the insurrection, kidnapping,
terrorism and destruction." Nader released a three-step strategy for
withdrawal earlier this week. See www.votenader.org for details.

serve just as well in this classic southern delicacy.
The sandwich originated in New Orleans, where an abundance of abortion clinics
thrive and hot French bread is always available.

2 cleaned fetuses, head on
2 eggs
1 tablespoon yellow mustard
1 cup seasoned flour
oil enough for deep frying
1 loaf French bread
Lettuce
tomatoes
mayonnaise, etc.

Marinate the fetuses in the egg-mustard mixture.
Dredge thoroughly in flour.
Fry at 375° until crispy golden brown.
Remove and place on paper towels.

Holiday Youngster

One can easily adapt this recipe to ham, though as presented,
it violates no religious taboos against swine.

1 large toddler or small child, cleaned and de-headed
Kentucky Bourbon Sauce (see index)
1 large can pineapple slices
Whole cloves

Place him (or ham) or her in a large glass baking dish, buttocks up.
Tie with butcher string around and across so that he looks like
he?s crawling.
Glaze, then arrange pineapples and secure with cloves.
Bake uncovered in 350° oven till thermometer reaches 160°.

Cajun Babies

Just like crabs or crawfish, babies are boiled alive!
You don?t need silverware, the hot spicy meat comes off in your hands.

6 live babies
1 lb. smoked sausage
4 lemons
whole garlic
2 lb. new potatoes
4 ears corn
1 box salt
crab boil

Bring 3 gallons of water to a boil.
Add sausage, salt,

3310. Radio control transmitter - interference problem

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-22 23:02:46 UTC
From: pvenkman@hotmail.com
Message-ID: <791aa995.0404221502.39000ca4@posting.google.com>
Source record: 26545

This is somewhat off topic; I apologize, but it seems like the people that hang out here might actually be able to help me with my problem.

I fly radio control gliders. I recently purchased a new transmitter (a Royal Evo 9 with synth module, for those that might care). I'm in the US so this broadcasts on 72MHz.

I have problems with this transmitter at one particular flying site that's right next to a military base. The xmitter is fine at other locations, and all the gliders respond just fine to my 'old' xmitter at this site. I've done a bunch of things and it really is just the new xmitter at this particular flying site.

It seems like there must be an interference problem with some signal being broadcast from the military base. I've tried to shield the transmitter without much improvement. That makes me think the offending signal may be coming in through the antenna.

Being relatively naive electronically, it seems like I could simply insert a filter between the antenna and the rest of the transmitter that passes through the 72 MHz signal but blocks everything else. However, I'm smart enough to know I'm not that smart. That's why I'm here.

Is it as simple as finding a filter that passes 72 MHz along and splicing it in to the wire going to the antenna? Is that likely to cause other problems (transmitting on the wrong frequency, overheating the RF module due to impedance mismatch, sudden death)? Assuming I can't find a filter that passes along precisely the frequency I want, is it OK to put filters in series (like a high-pass plus a low-pass)? And finally, am I just totally missing the boat here with this idea? I'm open to other suggestions.

> And finally, am I just totally missing the boat here with this idea?
> I'm open to other suggestions.

First, you can really mess things up by playing the filter game, so
don't do it unless you need to.

Second, it may be that the transmitter has a weaker signal, or that it
is a bit off frequency. Since your average military base has about a
gazillion different transmitters it's likely that there is some spur
being generated at 72MHz, or a valid signal at your RX's image
frequency. If your transmitter is a bit weak than such a signal from
the base would have an easy time getting into your RX.

If you can get the receiver out of the plane (or if you can get to the antenna) do a range check with the RX antenna rolled up but with the TX antenna extended. I'd do this at some _other_ flying site. Check the range with the suspect TX and with a known good one. If it's significantly lower with the suspect TX then you can do all the filtering in the world and it won't help you -- but having the new TX fixed (or selling it and getting another brand) may help a lot.

My general impression is that ladder filter terminating impedances tend to be based on the general frequency range of the crystals.

I built some 5.000 MHz ladder filters that work best with 270 ohms termination, while a filter I read about in an article which was at 12 MHz had 50 ohm impedances.

Of course, one can work with either termination....

In my case, I had calculated that 5.000 MHz IF and 1.2 MHz VCO would result in a 7 MHz transciever with VERY few mixing spurs anywhere near a frequency that would bother my design.

So, in general, I think the frequency of a ladder filter can be low or high, and used for either SSB or CW. But, mixing spurs and so on should be considered when choosing an IF.

There's a good article about building ladder filters in QRP Power. Designing and Building High-Performance Crystal Ladder Filters by Mahkinson, N6NWP. Was originally in QEX for Jan 1995. QRP Power also reprints an article by W7ZOI, Refinements in Crystal Ladder Filter Design, from June 1995 QEX.

Mahkinson says "Unfortunately, the required termination resistances of filters built with [color-burst] crystals may exceed 10k ohms, which necessitates an impedance transformation with a very high ratio (for a 50-ohm system.). As a result, very high voltage levels may be developed at the filter input, which may cause an overload condition. In addition, the required values of the coupling capacitors may be under 5 pF, making construction difficult due to stray capacitances. For these reasons, crystal filters with center frequencies under 6 MHz are not recommended."

"The usef ful upper frequency limit is determined by the influence of stray capacitances at frequencies above 10 MHz and by the limitations imposed on the VFO circuit for multiband HF operation. Consequently, the recommended frequency range for an HF SSB crystal filter is between 6 and 12 MHz.: The remaining criteria for the crystal frequency selection are the crystal Q and the price."

Hi Ken,

I have built a lot of crystal ladder filters over the years using methods and tools provided by W. Hayward W7ZOI, J. Makhinson N6NWP and others. Some filters are simple while others can be considered as high performance ones.

Among the several papers dealing with the subject, I strongly suggest you read the following :

- A Unified Approach to the Design of Crystal Ladder Filters, W. Hayward, QST May 1982, pp 21-27

- Designing an Building High-performance Crystal Ladder Filters, J. Makhinson, QEX January 1995, pp 24-29

- Designing and Building Simple Crystal Filters, W. Hayward, QST July 1987, pp 24-28

You can also have a look at my Web site : roland.cordesses.free.fr where some designs are presented with their measured characteristics.

Hello to all

Just downloaded and am playing with psk31 software. I can receive ok as I have a cable for that(standard plug to plug). I would like to transmit but do not have the cable. Looking to homebrew something simple until I can afford the Rascal GLX. I mean something real simple like just some wires plugged to the appropriate pins on my mic jack. I have an IC 718. I just don't know which pins to go to. I'm thinking I want to trigger the vox . . . That just sounds like the easiest way. I do have some homebrew experience as I built a 20meter rockmite into an altoids can. . . and it works. Minimal, but I am fairly new to this. Licensed under a year.

Thanks for any suggestions

Fred, my reaction when I first read the instructions was, hell, I get a wrinkly finish every time I paint somehing, I just never dared calling it a wrinkle finish, I called it another desaster...

I checked the hardness of the coating after it had dried hanging over my wood stove, which isn't running full tilt anymore, and there was still some softness so I threw it in the oven, brought it to about 200F and then shut it off, leavig the painted item inside.

That was yesterday and when I tested that piece right now it had markedly improved the hardness of the paint, actually I would say it is an excellent coating.

So success I guess, and I am already looking around the cabin to see what I could wrinkle up next.

When I first had the problem I sent the transmitter back for service -
they didn't find anything wrong, but tuned it anyway and sent it back.
The problem still existed, so I got them to replace the transmitter.
Still the same problem.

At other flying sites the new transmitter actually range checks better
than the old transmitter when checked against multiple different
receivers. For these two reasons I don't think it's that this TX has
a weaker or off-frequency signal.

Lots of other people fly at the same location with a variety of
equipement with no trouble. I've flown a variety of different gliders

there with my old transmitter and never had a problem. I really don't think there's a conflicting 72 MHz signal.

It really is just this transmitter at this particular site - other transmitters at the same site are fine, and this transmitter at other sites is just fine.

Is there any way to make this work?

AD sends free samples when you order through the web ,destined for a US address
I did that through a relative in LA who send the samples privately to me here in Scotland.

However a ham working for AD -UK commented on this NG that AD-UK would be sympathetic to requests for free samples ,but I haven't tried that route as yet.

Although a galvanic hook-up is considered OK by many , galvanically
separated connections between soundcard and transceiver for RX , TX aswell
as PTT are recommended.
It can be simply done by means of 2 small audio type of transformers a few
resistors and trimpots ,usually from a junk box ,ex transistor radio or
modem ,with the PTT through an opto-coupler.
If you are interested I can send you a scanned image of a simple circuit
diagramme ,which I implemented myself and is working well .

Not without more information, which was why I suggested a test.

Did you do the range check against the other transmitters with the TX antenna collapsed? If so, then you've done a fine test of how well your TX will work compared to others -- with everyone's antennas are collapsed. If you normally fly it with the antenna _out_ then you need to test it that way, and find some other way of attenuating the signal to the receiver -- like rolling up _it's_ antenna.

You obviously have a problem with that particular TX, which is why I'm suggesting a look at the TX first. Another question you can ask is does the TX have the same problem with other receivers? On other frequencies? Do you have another plane with a different brand receiver, or a buddy with same, that you can try at the problem site? This may be a valid thing to try.

Hi, First time using the ladder line, Please offer your opinions?

I have the 50 foot tower, it is right outside the shack window, so will be drilling the two small holes in the sill, then fishing through approximately 12" or 18" then replace the spacers to keep the distance between the leads constant. That leaves the remaining 98 feet outside of which I need a distance of approx 35 or 40 feet of the ladder line to reach my center fed 80m or two wires 66feet each leg. What are my options with the left over 50 feet (approx) of ladder line? Coil it up? Cut it? And what are the rules about keeping the ladder line away from the tower and steal guy wires that are not insulated? I only want to do this once now and first time using the ladder line, all suggestions appreciated, thanks.....

You didn't say, but if that "military site" is an airport, there's a localizer beacon that's probably just off the end of the runway and is on 75 MHz. Could readily be strong enough to give your receiver trouble.

I'd suggest cutting off most of the excess, but leave some slack in case you need to redo the terminations.

As for the trim, I'd leave at least two inches of space to any surrounding metal. Nothing is very critical for 80 meters anyway; in fact, using coax would be easier and probably work just as well. That's what I do.

I think everybody would be better off if I stayed out of the discussion on
surface mount antennas.

Yes, I agree about trying it as it is. If you're happy with the performance
as it is, no reason to change at this time. You could make the effort later
if your requirements change.

John

In article <791aa995.0404221502.39000ca4@posting.google.com>,
P. Venkman <pvenkman@hotmail.com> wrote:

| I have problems with this transmitter at one particular flying site
| that's right next to a military base. The xmitter is fine at other
| locations, and all the gliders respond just fine to my 'old' xmitter
| at this site. I've done a bunch of things and it really is just the
| new xmitter at this particular flying site.

You haven't actually told us what the problem is.

Is the computer in your transmitter crashing? (interfering with the transmitter)
Are the servos in your plane jittering? (interfering with the receiver)
Are you seeing reduced range or something? (interfering with the receiver)

| It seems like there must be an interference problem with some signal
| being broadcast from the military base. I've tried to shield the
| transmitter without much improvement. That makes me think the
| offending signal may be coming in through the antenna.

We'll need to know what the actual problem is. Shielding your
transmitter isn't going to do much unless the interference is actually
affecting your transmitter (possible, but unlikely) rather than your
receiver.

| Being relatively naive electronically, it seems like I could simply
| insert a filter between the antenna and the rest of the transmitter
| that passes through the 72 MHz signal but blocks everything else.

If the problem is interference to your receiver, doing this at your
transmitter won't help at all. You'd need to do it at the receiver.

Some people have had good luck simply wrapping their receiver (just
the receiver, not the antenna) in tin foil. Twisting the servo and
power wires round and round can also help reduce interference to the
receiver as well, and you can get chokes to wrap your servo wires
around as well.

Very very few people put additional filters on their R/C receivers.

Are there any pager towers nearby? Pager companies use the spaces
between the R/C channels to talk to pagers, and can use hundreds of
watts -- this has definately been known to overload R/C receivers and
crash planes. (In that case, the fix would be to 1) do the tin
foil/choke thing and 2) try a different frequency. (Your transmitter
is synthesized, so all you need is a new receive crystal.)

| However, I'm smart enough to know I'm not that smart.

That's a pretty good sort of smart to be! :)

| Is it as simple as finding a filter that passes 72 MHz along and
| splicing it in to the wire going to the antenna?

Probably not, unless your problem really is with the transmitter
computer crashing.

Which receiver are you using? The cheap park flier ones don't handle
interference well at all.

Do other people fly at this site? Your radio should be able to talk
to any plane, so try switching frequencies and picking the proper
shift and see if you can do a proper range check with their plane.
(Or another plane if you have more.)

You might also try asking in rec.models.rc.air, though they'll
probably tell you the same things I did.

(And yes, I fly R/C too.)

Don't sell yourself too short on the programming end.

You might sneak a peak at

http://www.picaxe.orcon.net.nz/

He has code for a PICAXE-08 for a 35 word per minute CW IDer.

He is using a simple and cheap controller from http://www.picaxe.co.uk
which is $2 to $3 and can be programmed again and again using simply a
PC COM port and two resistors. The software free from the PICAXE
site.

I have code samples for more complex PICAXE devices at
http://www.phanderson.com/picaxe/picaxe.html

Barring using a processor, I think this would be one difficult
problem. With the processor it appears it can be done with a single
8-pin PICAXE.

If you go to their website and sign up for their mailing list,
you will get a 'bingo card' every few months that you can send
back for free samples and info on new products, which often
includes DDS circuits, as well as A/D, D/A, and op amps. I have
also got samples of these, and some of their analog switches,
wide band amps, and mixer circuits. BTW they also make an
interresting driver amp for ADSL that looks like a low power
linear rf final amp good for a QRP rig.

We've seen so much about measuring the crystals and then doing calculations
in recent years, that it's easy to forget that hams started using crystal
ladder filters about thirty years ago. Make that a quarter century ago.
The fifth edition of Pat Hawker's "Amateur Radio Techniques" (copyright
1978) and references a number of articles in the France and the UK from 1976
on.

Memory tells me that when such filters started showing up in US publications,
namely QST, it referenced at least some of those articles, but then with
time the key articles have become the later onesin QST.

The synopsis in ART shows some standard designs, and you are supposed
to scale the components for your choice of crystal frequency. And no
mention there (though perhaps it was in the original articles) of
matching crystals. This is rule of thumb work.

>I looked it over, and have a pretty good guess, but I'm not certain.

IMHO, it to me as if:
Q1 is the local oscillator VFO
Q2 is the mixer (it's the only xstr that gets anything from Q1;
because of capacitors C9 and C10, the bottom end of R3 and the
bottom end of Q3 are essentially at ground potential to RF)
Q3 is the RF amplifier
Q4 is the AF amplifier
Qrest are elements of a push-pull AF output amplifier

"Short Circuit' and 'Leak' are not the same thing.

If you want a short circuited diode, just replace it with a piece of wire.

If you want a diode that leaks, put a resistor of the appropriate value in
parallel with the diode.

A severely overheated junction will usually look much like a piece of
wire. Doing this with excessive reverse voltage may work quicker than
excessive forward current, which often destroys the case as well.

If you're careful and have the luxury of a little practice to build technique, you can use a heat gun (hot air) to reflow solder SMT parts, but it takes solder paste rather than wire solder (which requires some care in handling and storage), and it does take practice to get the feel for your particular heat gun and develop the technique to get the best results.

Another technique is the "toaster oven method" ... search the Yahoo groups for "ez-bake" for a message thread with a wealth of information.

Also keep in mind that on SSB, a typical meter reading will be 50% output power or less as the meter will be reading average power. If it reads any higher, you are almost certainly overdriving the mic. If your power output is set at max and your mic gain & speech processor are set so that the ALC reading is between the lower and upper limit, then your radio is functioning correctly and you should not try to drive it any harder.

tks in advance, Artur.

3351. Icom 730 Preventative Maintenance Questions

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-25 16:50:26 UTC
From: Michael Brown <mabrown@qx.net>
Message-ID: <A7mdnWjhu7ijcRbdRVn-tw@qx.net>
Source record: 26588

I recently purchased an Icom 730 HF radio. This is my first HF rig evn
though I have had my Extra class license for about 2 years now. I noticed
on the Icom web page that there are several preventative maintence tasks
that they recommend performing on the IC-730 due to the age of these rigs.
I am looking for anyone that may have performed these tasks on the IC-730
that might be able to give me a basis walk-through of how I need to go about
taking the panels off the radio to gain access to the RF unit in the radio.
Here is what is listed on the Icom web page that they reccomend doing to the
radio:
1.) On the RF unit, resolder the J2 and J3 connectors. Due to the
relatively thick coax cables on the connectors, these solder joints tend to
crack with age and cause intermittent transmit and receive problems.

2.) Make sure the receiver preamp works. If inoperative, replace relay
RL1 on the RF unit. Install the factory update to prevent relay failure.

3.) Check transistor Q5 on the RF unit. If it is a 2SC945Q, replace it
with the improved 2SC2878B to prevent spurious output from the transmitter
and failure of the driver transistors. If Q5 is a type 1636, it doesn't need
to be replaced.

4.) Clean the RIT pot and switch with tuner cleaner. These controls
are usually noisy and erratic, making the RIT hard to use.

5.) Tighten the chrome-plated PC board mounting screws. The screws and
spacers tend to come loose if the radio is used in a high-vibration, mobile
environment. Don't forget to tighten the screws on the logic and IF units
located beneath the main unit.

6.) Check the bandwidth coupler for proper tightness.
Tighten as needed.

I'm sure the first step of re-soldering the J2 and J3 connectors on
the RF unit I can probably handle if all this involves is desoldering the
connectors and resoldering them. I'm not so much concerned about the
receiver preamp working, but does anyone know if Icom still stocks parts for
the Icom 730? The third step reccomends swapping out the Q5 transistor on
the RF unit if it is a 2SC945Q transistor and replacing it with a 2SC2878B

transistor to prevent spurious output from the transmitter and failure of the driver transistors. How hard would it be to replace this transistor? I would assume it would involve desoldering the transistor and replacing it with the new transistor. Would I just need to get a 2SC2878B transistor and some heat sink compond to replace this transistor? Where would get the 2SC2878B transitor? Can I order one for Mouser, or would this have to be ordered directly from Icom? Step 4 involves cleaning the RIT pot with some tuner cleaner, probably the easiest step. How do I locate the RIT borad to clean the pots? I would assume here too that all I need to do is to spray a shot of contact cleaner in the holes of the pot and switch on the RIT unit? Step 5 reccomends tightening all of the screws on the PC board. Hopefully I can handle this step if I can get access to all of the srews to tighten them. Step 6 reccomend checking the bandwith coupler for proper tightness and retightening it if needed. Where is the bandwidth coupler located inside the radio? What tools would I need to tighten it?

I thought I would post these questions on the newsgroups to see if anyone that is a little more technical-minded than me could walk me through performing these tasks. I have downloaded an instruction manual and service manual for the IC-730, but I thought maybe someone who might have a 730 and has performed these tasks could tell me how do them a little easier. The last thing I want to do is screw up a good radio. Thanks for reading my long post. Please e-mail me if anyone can help me out with this. Thanks!

interesting????!!

will investigate more..

question..how do you put 100 sm parts on board and get it to oven???does the water based solder act as glue till it melts??

does anyone have a few transistor recommendations..
looking for 1w at vhf (2m)..must be surface mount..

dont mind using 2 in parallel..

g0zen
p.s. preferably not mrf as hard to get here..

needs to be 15v ce gain 10db+

==========

Suggest you check with Mainline Electronics - Leicester , tel : 0116 286 5303

They highly likely have surface mount VHF power transistors from Motorola (MRF series) and Philips (BLY series) in the 1 Watt ,10dB range.

3356. 4 pin VRs

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-25 22:08:54 UTC
From: Lou <FFSTA17NO@SPAMACCESS995.COM>
Message-ID: <WFWic.3401$WC3.34530@ord-read.news.verio.net>
Source record: 26593

I've been looking for a 4 pin voltage regulator. I have a particular number in mind (uA78HG), but so far as I know, they're not in production anymore. I've looked in a couple places on line for a 4 pin job, with no luck. Since the one I "need" seems to be gone for good, right now I'm willing to use any 12 vdc - 15 vdc 1 Amp or more voltage regulator to get my power supply going to any extent - rather than leaving it collect dust or tearing it apart.

Failing finding a VR of my needs, I guess I'll have to redesign this thing to work some other way. I thought a last minute search may produce something to make life easier. Any ideas? With all the crap I have here, I could build a few power supplies (probably). But never ever - do I have the part "I" need.

Lou

But they were never popular. Occasionally, there'd be an article in the hobby
and/or ham magazines about them, but they rarely made it into published
construction articles. Sure, that doesn't reflect whether or not something
is used commercially, but it does suggest that there was something about
them that never caught on.

The question to ask is why you need the four terminal regulators.
What is it that makes you want to use one instead of a three terminal
regulator? The LM317 (and 337 for negative voltages) is a variable
three terminal regulator, and far more common, not just now but
forever. Not enough current (though I didn't think the 4 terminal
regulators were particular better than the average 3 terminal regulator
in that regard)? Then pick a regulator that does have better than
usual current. You could find them years ago, though not so commonly,
and I can't think why they wouldn't be around still. Or use an
external transistor to boost current. Or there is something verys
specific about the four-terminal regulator that you need, but in order
to come up with a workaround, you need to be specific of the need.

If you just need a regulator, virtually anything will fit in there,
and you just wire it properly and ignore the fourth terminal.

Lou -

I see from the Internet that this is not a new question.

] UA78HCSC and UA78HG
]
] Both of these numbers were found on 2 separate yet supposedly identical
] parts/units. They were 4 pin regulators used in a 5-15VDC 7 AMP Power
] Supply. Now, the HG number came from the manual itself for the power
supply
] I purchased originally. The HCSC was on a spare unit I bought - found on
] E-Bay about a year ago. It may have been replaced and for all I know not
] quite up to par with the HG. I've never run the spare unit through it's
] paces yet. I don't have any listings to confirm or deny this. BUT if
someone
] has these parts and willing to sell them, or know of a source thereof, I'd
] be happy to hear from them. OR something equivalent. As the other
gentleman
] alluded to, I don't want to have to "redesign" these power supplies.

IF this regulator is a TO-3 case, why not use a National LM317 (or 350, 338) adjustable regulator?
It comes in a TO-220 and TO-3 case style (as well as number of surface mounts)

a colleague has a little gizmo which grabs onto small lamps used in pushbutton indicators and switches, etc. He doesn't recall where he got it.

it is marked: MICROSWITCH 15PA19 LAMP CHANGER

where to buy this, or similar?

Hi,

If this is of any help, the service manual (12MB) for
the IC-706MKII may be downloaded from here (12MB) -

http://www.cqham.ru/ftp2/ser_ic-706mk2g.pdf

Perhaps you can then find some way of increasing the
microphone circuit gain.

Well, there a couple of different sorts of tools which do this job.....

http://catalog.sensing.honeywell.com/datasheet.asp?FAM=nawds&PN=15PA19 is a drawing of the OEM tool you mentioned from Microswitch (which has been swallowed up by Honeywell, so I'm not sure it's even still available given the caveats on the top of the webpage --- the drawing is dated 1958 & 1959 !!!).

http://shop.store.yahoo.com/tmt/lamextmtn553.html shows a fancier kind (albeit a bit pricy, like most things from that outfit).

Also look at the bottom of the webpage http://www.tecratools.com/pages/telecom/telecom_handtools.html for what looks to be the same sort of thing for less $$.

There's also a kind of lamp extraction tool which looks like a U shaped piece of metal ..... go to http://www.mouser.com/catalog/618/914.pdf and see the item at the bottom of the webpage called "lamp extractor tool".

And one which looks like a metal tube with a couple of splits at one end, and a plastic cap at the other ..... take a look at http://www.mouser.com/catalog/618/917.pdf on the bottom of the page under "lamp extractor" in the accessories section. Might be the closest to what your friend has, but you need to be sure it fits the lamps you want to pull.

Finally, I have seen el-cheapo sets of lamp pullers (I think I even have one somewhere in my tool drawer) at hamfests, flea markets, etc. at the tables which sell all the various tools & gizmos. Also might be worth checking with an outfit like MCM Electronics or Ocean State Electronics which caters to the industrial/electronic repair trade .... they often have this kind of generic item. Even if you can't find it on their web catalog pages, would be worth a call on the phone.

May also want to do some googling for "miniature lamp puller", "minaiture lamp extractor", etc. and see what turns up.

As I tried to imply, I thought I would take a last shot to try to find the "exact" match. Seemed to me, someone once suggested that these units were still selling over in the UK. Failing that, I would have to redesign this thing to work another way. The ideas submitted are great and well... it's off to the parts bins to see what I can scare up. My luck, everything but what I need.

Thanks again for all replies. It is appreciated.

For some applications, a few inches of heat-shrink tubing works well for
this.

The wiring pin out is here, if that helps at all:
http://www.mods.dk/view.php?ArticleId=2290

1. microphone output white
2. +8 VDC input red
3. frequency up/down blue
4. no connection
5. PTT yellow
6. GND (PTT ground) black
7. GND (mic ground) shield
8. No connection

You need a compelling reason NOT to use a 3 terminal
chip to replace the 4 terminal thing. For example,
an LM317 and 1 resistor and 1 pot creates a variable
regulator. 3 components - top that with a 4 terminal
regulator. There's no design to do. Go to the datasheet
and the schematic is there.

Source record: 26459

Hi OM's,

I need some help to identify a kind of communication ic,
I found on a surplus market last weekend.

I get a box of them and it's looks like a high quality part.

The part is labeled as

SGH XX 01.03 <long number>

where XX means:

02,03,05,07,08,09,10,11,13,14,15,16,17,18,19,20,
21,22,23,24,26,27,28,29,30,31,35,36,50

marked with a blue dot on the case

18 Pin in square 2x4 and 2x5

The case is made of metal 34 mm x 21 mm x 20 mm
in size.

Have someone an idea which kind of ic could this
be? (for an oscillator it has to much pins)

Suggestion re lamp remover.
I have somwhere a tool that was used to remove the small (about one quarter inch diam) cigar/tubular shaped telephone switchboard lamps.
Basically it was split metal tube, with a wooden handle. The two 'halves' of the metal tube were tightened slightly by a pushing an angled lever. Thus lamp could be withdrawn straight out.
Similar idea, of correct dimensions, might work for say dial lamps which are bulb shape and either screwed into miniature Edison or given a quarter turn into bayonet socket.
Someone such as Bill Turner may even have made such an item? Hard plastic tubing might be an alternative to metal?
Terry.

3374. Quadrature mixing from 2xLO PLL?

Source record: 26461

Hi group,
An associate is proposing a mixer design that I'm having a hard time understanding. I did some Google searching and haven't found an answer, so perhaps some kind sould can help.

The basic porposal is to generate a clock at twice the LO frequency, divide it by two and use some sort of differential mixer circuit. This is for wideband (broadcast) FM reception. He says that the key is the use of differential circuits within the mixer. Of course, this is intended to be used with quadrature demodulation.

Sitting down and thinking about it, I could see how it would work if one were to take the rising edges of the 2X LO clock for one phase and the falling edges for the 90d phase, but it seems like doing it that would way would likely result in the I+Q not being perfectly orthagonal due to things like different delays in rising vs falling edge logic, imperfect duty cycle, etc. And even then it wouldn't need to be differential.

Well, if anyone has a suggestion for a mixer architecture that does what he says (ie uses 2x LO clock and requries differential circuitry) then I'd appreciate the help.
Regards,
Matt

> a valid thing to try.

I've done the range check with the antenna in; under normal
circumstances the range is further than I can see with the antenna
out. I can try rolling up the receiver antenna.

I've tried the transmitter with 5 different receivers (4 different
brands) on 5 different frequencies, all with the exact same problem.

At one point I had two different receivers (different brands) on the
same frequency turned on, and when they glitched they both glitched in
exactly the same way (rudder went hard right on both models, for
example). This isn't proof, but in general you wouldn't expect two
receivers to glitch in exactly the same way if the problem is
interference at the receiver.

It's not an airport, but who knows what they have blasting away on any
number of frequencies. I don't have the equipment to check it out.

The computer doesn't crash; the servos jitter badly; range is reduced
to zero, as the jittering starts immediately.

I know reading this you're going to think it's the reciever, but
please read through my other posts. It's not. I've tried 5 different
recievers (4 brands) on different frequencies, and with my old
transmitter all are fine and with the new transmitter they all glitch.
However, it's only at this particular site - anyplace else all the
receivers are glitch-free with the new transmitter.

No pager towers, at least that I'm aware of. However the military
base has a large number of antennas and who knows what they're
broadcasting.

>
> | However, I'm smart enough to know I'm not that smart.

Well, the computer doesn't crash. I finally ran into another guy at
this site flying with an Evo; he had the crystal instead of the synth
version, and he had no trouble at all. I'm working on getting a
crystal module to try.

>
> Which receiver are you using? The cheap park flier ones don't handle
> interference well at all.

I've tried two Airtronics, an old RCD (they're Hitec now), a JR, and
an FMA M5. With the old transmitter (an Airtronics) they're all fine;
anyplace but that site they're all fine with the new transmitter too.
Try the new transmitter at that site, and they ALL glitch.

>
> Do other people fly at this site? Your radio should be able to talk
> to any plane, so try switching frequencies and picking the proper
> shift and see if you can do a proper range check with their plane.

> (Or another plane if you have more.)

This is a pretty popular site. I've seen lots of people flying lots of different types of equipement at this site with no problems. I've flown four different planes there with the old transmitter with no problem.

>
> You might also try asking in rec.models.rc.air, though they'll
> probably tell you the same things I did.

I've asked a variety of places without much luck. Mostly it's been a pattern of demonstrating I've tried all the reasonable things and it's not a problem with the reciever, followed by suggestions that I either just get another radio or fly at a different site. Neither of those 'solutions' are appealing, so I was hoping someone on this site (being more technically knowledgable) might have a better idea.

BTW, I completely understand why people think it's the receiver to start with. It practically always is. I tried three different recievers myself before I finally started to think just maybe it was the transmitter.

If two receivers are receiving exactly the same interference at exactly the same time they may glitch the same way.

Since it's a synthesized module and should be easy to do, have you tried it on a different frequency (with appropriate RX, of course)? Obviously something screwy is going on, if it's limited to one frequency you may be able to just switch to a more benign frequency and have fun.

You could switch to flying control line, but that gets difficult with gliders.

MicroPac is listing their part number 52150/52175 as a replacement for 78HGA
http://www.micropac.com/pdf/products/VR52150-52175.pdf

MicroPac's statement on obsolescence:
Due to the many problems our industry is dealing with today due to
obsolescence issues, and the decisions made by many of our competitors to
exit the military marketplace, Micropac Industries, Inc. want to take this
opportunity to assure our valued customers that we will continue to support
their requirements for high-reliability products. Our Company has no
intention of making obsolete any currently produced devices. Our charter is
to continue to support our customers with the same quality products as we
have successfully produced for more that three (3) decades.

That should work !

3382. DCTL Antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-26 20:56:44 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0404261256.71e27686@posting.google.com>
Source record: 26469
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

The DCTL Antenna design is at http://www.n5nw.org/antennas.html

The MFJ magnetic loop antennas are quite expensive and don't cover the low bands. Homebrewing magnetic loop antennas is very tricky due to the need for WELDED connections and special capacitors that can handle thousands of volts. These tricky issues probably explain why magnetic loop antennas are so expensive. (I'm also surprised that MFJ doesn't make a larger version of the magnetic loop antennas for 80m that's perhaps 6 feet wide and long.)

The DCTL Antenna is a loop antenna made out of twin lead, and it has received rave reviews. From what I've heard, it performs well compared to other antennas of a similar size. (Obviously, it can't be as good as a full-size loop or dipole.) I believe the DCTL Antenna uses the shorted stub and open stub as loading capacitors. It's not as small as the magnetic loop antennas (4-foot wide square for 40m instead of 3-foot wide loop), but that allows the DCTL to have more radiation resistance (so that welded connections aren't needed).

Has anyone here constructed and used a DCTL Antenna? Some questions:
1. How seriously is it affected by nearby metal? I know any antenna is affected, but some are affected less than others. For example, monopoles are affected less by nearby metal. This is why apartment dwellers using a
balcony with metal railings are generally advised to use a monopole antenna and use the metal railing as the antenna ground. Mobile antennas are always monopoles instead of dipoles.
2. How do you insulate and reinforce the wires at the feedpoint? I think this could be a mechanical weak spot. Would coax sealer help? Epoxy glue? Perhaps a non-metallic box with holes drilled in for the wires?
3. Could the length of the open stub LC be adjustable to modify the resonant frequency? Perhaps one could put in a connector (Molex, PowerPole, etc.) and then add in a small open stub. Perhaps something similar could be done with the shorted end as well. Perhaps one could add ferrite chokes to electrically (but not mechanically) terminate the stub, as the RF would be mostly on the outer surface of the wires. With these adjustments, it may even be possible to make the antenna multiband. Of course, this would require deviating from the provided formulas.
4. How much feedpoint resistance can one expect from the DCTL? The author suggests using a 6:1 balun. So it sounds like the DCTL Antenna should be about 300 ohms. 300 ohms is about the characteristic impedance of twin lead. But I thought that smaller antennas normally

have feedpoint resistances WELL BELOW 50 ohms, which is an even farther cry from 300 ohms. Or do those stubs work as a matching network as well?

3383. 250+ degree meter movements?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-26 21:52:53 UTC
From: Tom Kreyche <tkreyche@well.com>
Message-ID: <Vwfjc.42683$w96.3196919@attbi_s54>
Source record: 26470

Does anyone have sources for analog meter movements that can rotate at least 250 degrees? I'm building a custom rate-of-climb instrument for my glider.

I found one source at http://www.us.yokogawa.com/MI/ but their smallest off-the-shelf unit is a bit large at 50x36mm. It uses taut band technology.

I've been trying to find a source for air-core movments but web searches only show up people selling automobile tachometers. I'd can drive the meter with PWM or DAC or whatever.

Thanks, Tom

Possible; however, they were different brands and different circuits,
and it's less likely that some random interference would cause them to
act the exact same way. The same brand wouldn't surprise me.

I've tried 5 different frequencies; all act the same way.

So what's the matter with an automobile tach? They're all electronic
these days, so you drive them with a pulse train who's frequency is
proportional to the reading you want to see.

12000 feet = 12000 RPM (assume you can get one that high) = 200 rev/sec
= 400 pulse/sec for a 4-banger.

No I don't, but could you not turn a zero-center analog meter on it's side and
get rate-of-climb, or drop information.

==========
For many years I have used and still use a micro-torch with a well
controlable 'pointy' flame.
Last night I fitted a BNC plug and soldered the centre pin with the 'pointy'
flame' ,which I find easier than with the bit of a normal soldering iron.
Also desoldering is sometimes quicker with the micro-torch than with a
normal soldering iron, because of the instant high level of 'spot' energy.

For info of UK based readers : I use the Flame Master micro-torch available
from Maplin.

==========
Or borrow a handheld scanning receiver. It could well be that a nearby
transmitted signal ,not necessarily on or near 'your ' transmitted frequency
affect the RC receiver (which probably has limited immunity in respect of
strong harmonics/mixing sigs.)

Hi Jason,
I tried to make a DCTL antenna for 80 m from a 300 ohm TV twinlead.
Unfortunately, after I made some measurements, a strom approached and
I put the antenna down. I have never continued the experiments since
then.

> 1. How seriously is it affected by nearby metal?
Sorry, no experience.

> 2. How do you insulate and reinforce the wires at the feedpoint?
I used several layers of adhesive tape only, as it was a temporary
experimental installation. A better construction seems to be necessary
for long-term usage. One proposal is at
http://www.radiohc.org/Distributions/Dxers/dctl-antenna.html

> 3. Could the length of the open stub LC be adjustable to modify the
> resonant frequency?
The antenna is "fine-tuned" by the open stub. The formula given in
http://www.n5nw.org/antennas.html works quite well.

> 4. How much feedpoint resistance can one expect from the DCTL? The
> author suggests using a 6:1 balun. So it sounds like the DCTL Antenna

Despite that, the RF-1 bridge showed approx. 150 ohm impedance around
resonance. Maybe it is always one half of the characteristic impedance
of the twinlead used ? And remember, the input of the antenna is
balanced.

Might be kind of tough to pin down. IF they're using H.F. and probably up into the GHz region and maybe even as low as the L.F. area to transmit, any one of those transmitters OR a harmonic OR a clashing of all or any - could be causing the problem. Given he said Crystal control planes work there but not Synthesized units and given he said the planes operate ok elsewhere, leads me to believe that the synthesized receiver (all of those he has tried) is coming unlocked due to RF overload from something. Synthesized receivers are nice, but they do have their draw backs. I've had battles with them too in tight RF areas. Some places, a crystal IS better. Antiquated maybe, but if it works, what the hell..... Just my opinion. I'm not an RF engineer, but work around RF a lot. I've seen lots of weird stuff.

At the moment, BPL deployments are small and few in numbers ... their sphere
of severe interference is therefore limited.

However, with massive, nearly ubiquitous deployments, the interference will
end up being virtually everywhere ... that is the major concern.

Er... The dctl IS a magloop. A piece of paper, some elementary formulae
and
a few minutes of thinking might brighetn things up.

The dimensions of the magloop are more or less given out of the pf/m
beteween the twinlead conductors and the dielectricity constant of the
twinlead
material. A "classic" magloop can be any size.

Radiation resistance of the dctl, is, well, smallish to say the least.

The DCTL is not only a magloop, but a magnetical dipole. Magnetic
materials (such as iron) should be kept away! Non-magnetic materials
of course affects, but are not a disaster (given the poor performannce to
start with!).

The stubs can (and SHOULD, IMHO) be trimmed to get the resonance at
favourable frequency. The dctl is very narrow-band. If You have got a
wide-band SVF dip, the antenna Q is bad!

> network as well?

Feedpoint resistance does not equal radiation resistance. From a matching
point of wiev, what interest us is feedpoint impedance. As we use the
dctl also when there is no resonance, I propose it is feed by a balanced
output transmatch (same principle as a "zepp").

The feed impedance is a function of the twinlead feeder length, and the
stubs
(which are used to match the thingamajig). The conclusion is that feed
impedance
is individual and adjustable!

Radiation resistance is LOW, and remember that 300 ohm twinlead is lossy.

Message-ID: <flidnULwprFV4hPdRVn2gw@ecrii.com>
Source record: 26487

The problem is poor design of the switching system. It uses a triac with duty cycle control of the current. Since it switches the lamp on late in the cycle, there is a big transient each cycle.

It's an old design. I don't know if the newer ones are any better. I would think it had to mee FCC part 15 to be sold; how old is it? Talk to the manufacturer and the FCC to find out if it's still being sold.

About the only thing you can do is shield and filter, but shielding would make the lamp rather useless. If you are concerned about 7 MHz noise then better use filtering components that are effective at that frequency.

73, Bob

I had the same problem, and the only thing i could do to solve it was to
unplug the lamp.

I recommend against short-changing yourself, and your Customers.
This will take up your time, and if you don't charge enough, you will
eventually walk away, leaving your Customers stranded. Be fair
to yourself and your Customers by charging enough to compensate
for your time.

Hello,
Actually, the RF Chokes will act just as filters. I'll drow the
schematic in the computer and send you, if you allow.
The transmitter will work at 88MHz - 110MHz.
The oscillators are made from 18 AWG wire, 8mm of diameter, 4 - 5
turns.

Thanks

BPL hasn't happened yet on any type of widespread basis. So far there's really only been a few pilot programs in limited areas. I wouldn't put the brakes on your QRP work just yet.

In addition, no matter what the marketing hype is, there is a good chance that in many areas it simply won't be economically feasible or that it won't be able to effectively compete against DSL and cable access. Since BPL will be carried over unshielded lines, it will be subject to dropouts from all kinds of interference thus vastly slowing its effective speed, quite possibly below what is available with a simple phone line and dialup service.

Message-ID: <YSDjc.55191$um3.1067552@bgtnsc04-news.ops.worldnet.att.net>
Source record: 26494

I have an AM radio on an aluminum boat. The radio is shielded on six sides by aluminum. I want to mount an antenna on the boat and run coax inside and couple the signal to the ferrite rod in the radio. I'm thinking about an active whip antenna with a 50 ohm output. If I did this, I would have a coax with 50 source impedance at the radio! How do I create a 50 ohm load at the radio over the AM band? The radio has a 2-3/8" x 3/8" ferrite rod.

I would appreciate any other solutions to get a signal to my radio.

Mike

Well, I'd certainly be willing to give em a try. I e-mailed some guy that someone else suggested. He is a real ass hole. His reply was all pretty much jumping down my throat for asking. He asked, "did I think he was in business", "did I think his list was incorrect" - since I had pasted a portion of it in my e-mail "per his web site's instructions - to lead him to the list where the parts were listed." People like that, I don't need to deal with. He has exactly what I need, but he can stick them up his ass. I don't deal with ass holes. I don't need those parts that bad to kiss his or anyone else's ass. I'll be in touch privately.

Thanks,

Lou

That looks like a good way to go, it would sure beat trying to solder individual leads, but... it looks like the minimum order quantity is 10 tubes of solder, for $120 or so. (And these are the small 35g tubes. Digikey's are more like $800 for the minimum qty of 500g tubes.)

Anyone know a source for small quantity (1-3 tubes) purchases?

Source record: 26496

At this frequency for a receive application the impedance is not very critical.

However, if it would help you sleep at night you can put a 3 dB attenuator at the end of the coax to match the impedance.

For coupling into the receiver, wind a coil of wire big enough to go around the entire receiver. Perhaps 3 or 4 turns would suffice. Then place the receiver inside the coil.

If the signal out of the antenna amplifier is strong enough, you might get away with just setting the receiver next to the coil.

To clarify, the setup would be like this:

Antenna---->amplifier---->Coax---->attenuator---->Coil near receiver.

And if it was me, I wouldn't bother with the attenuator.

What I have done in the past is to tin the pads where the parts are going to be mounted and then I use two soldering irons. One on each pad and it pulls the part right down into a good position.

Ok ok I hear the question now. What about parts with more than two leads?

That is a valid and good question. Only tin two pads for that part and use the soldering iron on each one of the pads to get the part mounted and in position to finish soldering the rest of the leads one at a time.

Mike,
I didn't do anything but see this and since it didn't work any more,
take the loopstick and some other good parts out of it. A radio my dad left
had an RCA jack taped to the handle. It had about 8 turns of wire wound
around the ferrite loop stick antenna inside the handle. If the "coil
around the whole radio" seems poor, try this. What you do on the other end
of the antenna coax, I can't comment. I have only begun to play with
200-500kHz reception.

I just got a deal on ebay for 8.3886 mhz crystals (414 pcs for $9.99).
Should be able to make a few good ssb and cw filters out of that!
They look like std microprocessor types (hc49/u holders) though this
isn't a common microprocessor frequency. Guess I'll start with 100pf
coupling caps, any good guess on what the termination resistance might
be? (I'm looking for a bw suitable for ssb, probably about 2.1khz).
Hope this frequency doesn't have any bad mixer products (but I can
always pick either high or low side injection if necessary).

3417. 433MHZ modules followup

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-04-29 00:24:29 UTC
From: Joe <nuisancewildlife@nospamearthlink.net>
Message-ID: <1XXjc.16643$e4.4382@newsread2.news.pas.earthlink.net>
Source record: 26354

A week or so ago, I asked for some advice on using these modules to trigger my camera shutter remotely.

I first wanted to thank all who replied. I tried the PLL approach and it seemed to work ok until I connected an 'antenna' to the receiver. That seemed to produce a lot of noise that was able to overcome the PLL at times. I also tried a bandpass filter and had the same problem with noise. I finally broke down and bought the holtek 12D and 12E and have decided that is the optimum solution. The 'antenna' I refer to is just a 15cm piece of 20ga solid copper insulated wire, but it gives me a range of about 30 to 35 meters which is more than I expected.

So I am wondering about antennas. As I said, I am using a single piece of solid copper wire attached directly to the antenna input of the receiver and output of the transmitter. Why don't I need a ground too? I have been reading my radio amateur handbook, and I guess this antenna could be considered a dipole, but the book shows that I should have a ground connection somewhere, ie , like maybe dual conductor wire with one lead to the antenna output or input of the TX or RX, and the other to ground, then bend the tops of the wires at right angles (horizontal) at the right multiple of wavelength.

Any one have any ideas? I guess I am looking to maximize my range now.

TIA,
Joe

Actually, for the occasional prototype, the two-iron method, while a bit
tedious, works. (and while 0402 parts are a bit of a bear, even with my
aging vision I can handle 0805's and 0603's with this method ... but it
takes time and patience and I don't like to do a *lot* of parts that way)

You can also, with a bit of practice and care, use a "heat gun" to reflow
boards if you don't envision doing enough of it to justify the cost of
"real" reflow equipment.

I purchased a very nice and effective hot-air system for about $350 new on
e-bay (search on "reflow" - the brand I bought is "ATTEN" and it's
distributed by a company called "smtpros" if I recall correctly) ... and
I've also purchased a toaster oven for the "ez-bake" method ... do a search
on Google or Yahoo and you will find a Yahoo group on "ez-bake" with a long
thread of useful and informative discussion and hints.

Remember, for reflow you need solder *paste* ... available from a number of
sources on the web. I prefer the "no clean flux" kind, though I usually
clean the boards afterwards anyway ...

Sir:

From necessity I did this with well over 500 parts on two assemblies for radios that were prototypes. The people that had tried to do the assembly with the approved methods had set the solder paste on the pads, placed the parts in postion, both steps done by hand and then washed the boards before they vapor phased the boards. This department then went ahead and cleaned the filters out of the washing equipment, repasted the boards and just put the parts where they fit.

I got two blank boards and all the parts sorted out into envelopes in tote pans with clean prints of the parts list and a component layout with the task set to get it done in a certain amount of time.

Monday through Saturday I worked 16 hour days and then on Sunday I took it easy and worked 12 hours.

In addition to the surface mount parts I also had about the same number of leaded parts on each board.

When I was done I was told that there were a total of 5 errors between the two boards. It took about 2 to 3 weeks to accomplish this and several sets of batteries for headset radio.

There were times I would place parts on the bench in front of me, put the envelope back into the tote pan and could not see the parts. I would find them after blinking several times, place them and then get up to take a walk through the area to get things loosened up and relaxed a little bit.

This method I described is indeed a possible method. It has been done by others than myself and sometimes it is the most expedient method to accomplish the task.

The smallest parts available would make this method a challenge but it would still be something that could be done with some time and paitence.

Good luck on your project and I wish you the best Sir.

For many irons, you can also buy fork-ended solder tips that bridge over the parts. I made one by cutting and filing an old tip, and it worked OK for parts removal. However, it would need some co-ordination to make the tip contact the two pads without also knocking the part out of place.

The toaster oven looks like a much better method for a whole-board assembly project, except for two key problems:

1. Solder paste is expensive

2. Solder paste doesn't keep (seems to have about the same time constant as Horowitz & Hill's wet fish)

Those are big problems for occasional, low-volume users such as ourselves. So the questions are:

1. Where's a low-cost source of solder paste? (in various parts of the world)

2. How can we either store it so it stays fresh; or re-constitute it after it's gorn orf?

Hi guys,

Throw me a bone here.......
Although I only have my UK Foundation licence, I'm not quite a novice when it comes to circuits. I worked for many years as an IT systems engineer, can read a schematic, and understand what a circuit is doing.
What is really starting to bug me is trying to locate a source of information for alternative parts, especially transistors. I have acumulated literally hundreds of parts, but I can guarantee that for any given project I wont have the exact quoted part and will have to order in a part costing pennies with handling and delivery in pounds. Maddening to be sure.
Does anyone know of a site that gives a list of alternative or equivalent parts? As an example, I have hundreds of 2N2222 transistors but the requirement is for a single BC547 of which I have none. The datasheets would suggest that the 2N2222 would do the job, but is it always going to be a 'suck it and see'?

Any advice gratefully received.

Simon (MW3CUR)

==========

The genuine amateur, indeed the professional in thoughtful moments, looks at the parts pile and asks himself "now what can I make from that? "

Or he visits car-boot sales stalls and asks the same question.

A bird in hand is worth two in the bush.

A pound to a penny, after a tedius pencil and paper design and a prolonged search, key parts will eventually be found to be not available from anywhere. Or be too expensive. So change to another more satisfying design.

Inevitably, Economy Rules!

In addition to QRP, BPL could wreak havoc with mobile services -- here in NJ (JCPL is part of GPU -- GPU is part of First Energy -- what a marriage -- the 8/14/03 disaster coupled with Three Mile Island!!) there are some places where the interference from power line connectors, poorly maintained transmission just crackles. Fortunately BPL is unlikely here due to Comcast or Verizon's DSL.

> after it's gorn orf?

Solder paste must be kept refrigerated to maximize its shelf life. (read the manufacturer's storage and handling instructions CAREFULLY, both for proper storage for product longevity and for safety reasons)

Note: If you don't have a dedicated refrigerator and *must* use one you keep food in, you *must* take the *utmost* of care to do (at least) the following
before even *considering* putting solder paste in your (regular, food storage) refrigerator (and you should probably do this even if you have a dedicated refrigerator):

1) clean the tube VERY well after use to make sure no paste is on the outside
2) place the tube in a plastic "zip-lock" bag (which must not be contaminated with solder paste)
3) place the bag, with the tube inside into a plastic container with a tightly sealing lid (again, this must be clean and not contaminated with solder paste)

Doing this *very carefully and meticulously* will at least minimize the possibility of contaminating your refrigerator with solder paste particles, which are VERY small ...

Further notes: You should, at after each step above, THOROUGHLY wash your hands to assure that you don't transfer any solder paste to the outside of the bag or the plastic container. Use a fresh, brand new bag each time (they are cheap). Also wash the plastic container THOROUGHLY inside and out each time you prepare to re-store your solder paste (don't wash it in your dishwasher - do it manually and clean up afterwards as if you were cleaning up a hazmat spill). And finally, NEVER use the plastic container for food after you've stored solder paste in it, NOT MATTER HOW WELL YOU THINK YOU'VE CLEANED IT.

Ultimate note: If you have children in the home who could get into the refrigerator and get at the solder paste, you probably shouldn't even consider putting solder paste in your refrigerator where the children could get at it ...

DISCLAIMER: While I believe the precautions above to be adequate and use them myself, I take no responsibility for any consequences of a proper lack of care on anyone's part in doing what I describe above, or any inadequacy in my suggestions. Anyone following these suggestions does so solely at their own risk.

73,
Carl - wk3c

p.s. Additionally, anyone considering the "ez-bake" method of reflow soldering needs to understand the ABSOLUTE necessity of having a dedicated toaster oven that is NEVER used for food preparation. It, along with all soldering supplies should be used and stored in an area that is inaccessable to children (keeping in mind how inquisitive children are and their ability to get into things that you *thought* were secure or inaccessable).

Marshon wrote:
> Does anyone know of a site that gives a list of alternative or
>equivalent parts?

Not really... and if I did, I wouldn't trust it. They can't possibly know what is important in your particular circuit.

When the same device is made by several different manufacturers, each one may give it a slightly different label. The only worthwhile thing that so-called "equivalents" lists do is help you recognise the root number that they all share. Devices that share the same root number are directly interchangeable in most cases - because they are intended to be the same.

But devices with different numbers are usually intended to be different devices.

Be literal-minded about this: a true substitute can only be another device of exactly the same type. In all other cases, think of it as a *different* device that does *some* of the same things... namely, the things that you need in that particular circuit.

>As an example, I have hundreds of 2N2222 transistors but the

>to be a 'suck it and see'?

If you've actually compared datasheets, you've already done far more than most people. Think about what a transistor needs to do in that particular circuit, and trust your own judgement.

I made my own some time ago for two TO220 devices from a piece of Al
channel. It was much easier to mount on my PCB than any of the commercial
ones and had plenty of dissipation for my application.

I agree with Reg, since you hae so many you've nothing to lose except a little time and perhaps some smoke. I do many genereiuc swaps and the only thing that concerns me first is the polarity, size and power. If those are close I try it. I think in this case you're in luck as the first Google hit shows both transistors. Here it is:
http://www.electronics-ee.com/Electronics/Components/Transistors.htm

Its always frustated me why the UK had to use a different system for numbering similar things. Perhaps it's for the same reason we drive on opposite sides of the road, hi hi hi. Drving over there frustates me so mcuh I don't even try anymore unless there's no other choice but I do pick up UK numbered transistors whenver I see them at swap meets, just in case I can use it. So far I've only found a couple!

Let us know how it works and have fun

I appreciate the replies, but the problem is NOT with the receiver,
it's with the transmitter.

I admit this was more or less the response I expected, but I really
hoped someone would say 'oh, I had the exact same problem and designed
and built a filter for my transmitter that fixed everything, and I'd
be happy to show you how to do the same'. But thanks for the replies,
I do appreciate it.

Look, if the transmitter is "synthesized" i.e. not crystal bound, and it is suffering the problem only near the Military base, then it is pretty obvious that the transmitter is being overwhelmed by a stronger signal. IT CAN AND DOES HAPPEN! The minute signal of your transmitter milliwatts to a watt or so is most likely being swamped out by the mega watts they are using or the mixing of the signals is doing it. Either use a crystal controlled transmitter there, or quit flying there! They're not going to shut down for you to fly your model plane. You claim that is the only place it happens.... Soooooo! Maybe no one else flys in RF bombarded fields to have experienced the same problem that you're looking for the answers to. The answer is obvious. Crystal controlled or stop flying there.

I sure hope "solder paste" is NOT the same thing as "soldering paste flux",
or else my shoe-polish-size can of "Kester Soldering Paste Flux" (with a
hole in the lid through which I occasionally poke a soldering pencil)
that's been sitting on my workbench for at least the last 25 years hasn't
heard about those storage and handling instructions!

No, it is very small particles of solder in flux.

==========
You probably mean European instead of UK numbering system versus the US
system.
And also there is of course the Nippon numbering system.
To my knowledge there are only few commonly used transistors with a typical
UK numbering code like the ZTX (Ferranti ?) series.

'suck and see'
Sounds like a new Matel toy...

Simon,
You claim to be no dummy, so... You know what you have, so look at the application and take what you have that fits the application the best, then tweek away...er, uh, rather optimize for your choice. The 2N2222 will probably work on 99% of the projects anyway....

I vote... start suckin'...

When looking at transistors to see if one on hand would be a suitable
sub for one called for in a design the important paramters are the
max voltage ratings (VCBO, VEBO and VCEO), the current gain (Hfe) and
the transfer or cutoff frequency Ft ratings. If the device must handle
any power then look at the power dissipation rating (PD) and max current
ratings (Ic). Be aware that some ratings such as Hfe and Ft are
made under certain operating conditions, IE: a transistor could have a
low current gain at low collector current, but a moderate to high gain
at high currents. That's great for a power amp, but not so good for a
small signal amplifier. If you have a curve tracer (Heath IT-1121 is a
nice inexpensive unit that shows up on ebay from time to time, you need
an external scope for this one) you can identify unknown transistors.

No, Myron ... solder paste is a suspension of micro-spheres of solder in a
flux that makes a paste that is used for reflow soldering of SMT parts.

If you need that much gain, you're best off with an amp module from
Motorola or someone.

At VHF, 30mW in for 10W out will have serious stability problems if done
discretely and if not layed out just perfect.

I seem to recall a design using EXOR gates to divide the signal by two -
I cant remember the details. I recall however that the duty cycle of the
input clock was critical I have successfully used a Johnson Ring divide
by 4 Counter a few times to generate quadrature outputs from a 4X clock
signal. The duty cycle is not critical in this case as the clock counts
on a rising (or falling) transition of the input.
I am not sure what you mean by "differential mixer" Does this mean two
mixers with the inputs fed 180 deg out of phase? Of course at 100 MHz
you would have to use ECL logic.

Richard

They have a ton of "brick" modules by Motorola, Mitsubishi, etc. These devices are the cat's a**! They basically need DC power and In/Out pins hooked up. As others mentioned, some are for FM/CW and some are linear (SSB, AM, etc.)

==========
Suggest you consider Mitsubishi RF Power modules (still available)

for 144 - 148 MHz : M57713 P(max) =
10W (for linear duty)
M57719
P(max) = 21 W
M57715
P(max)= 20 W
or Toshiba SAV17
P(max)= 25 W
or Motorola MHW612
P(max)=25W

For 430 -450 MHz M57716 P(max)= 10
W (for linear duty)
M57729
P(max)=?
or Toshiba S-AU4
P(max)= > 10W

Not all the modules might be suitable for linear operation (SSB) so you have
to check with supplier.

Here in the UK a supplier still carrying these Mitsubishi power modules is
Mainline Electronics - Leicester
www.mainlinegroup.co.uk

An excellent book for homebrew transverters and power amps with the above
modules :
The VHF / UHF DX Book , edited by Ian White , G3SEK.

You can always look at the Elecraft XV transverter layout (e.g. 50, 144, 222
MHz)
- or just build the kit. The 70 cm version is due later this year - BUT
will require
a different board layout.
http://www.elecraft.com/XV/XV.htm

This design can handle .01 mW to 8 W input.

RF Parts is nice because they tend to have stuff you can't get anywhere else. HOWEVER, one caution ... if somebody else has it, somebody else will almost always be cheaper. Of course there are exceptions to prove the rule, but they are definitely the high-priced spread.

Some of those modules do look like they are -exactly- what OP was looking for, tho.

Yeah, for simplicity the modules rule, but it's hardly in the spirit
of homebrewing, is it? Whilst it's hardly a beginner's project, I
don't see why anyone who knows what they're doing couldn't build one
of these from discretes and have a lot of fun doing so. Where do you
suppose most of these "serious stability problems" are going to arise?

RF feedback between the stages is the biggest enemy. If it's well shielded
and maybe a bit of neutralization, he should have no probs then :-)

3452. ARRL CD ROMS under linux.

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-01 01:37:45 UTC
From: Ken Scharf <wa2mzeNOTTHIS@bellsouth.net>
Message-ID: <o5Dkc.48297$oN1.6090@bignews5.bellsouth.net>
Source record: 26393

For those hams running linux, I've found I can read
the ARRL QEX and QST View cd roms under linux using either
the Gimp or Open Office writer. These cdroms are scanned
images in tiff or jpg formats which import into either program.
By importing into an OO text document I can convert the articles
into PDF files and print double sided to my printer for
hard copy.

I started looking at writing a program to search the QST view
database found on the disks. The database on the disks up to
1990 (not sure about the 1995 disk) is an ascii representation
of a 3 table SQL database so I can create a MySQL, Posgres, or
similar SQL database to search. The QEX disk has a binary database
of which some sections are readable under vi as text that also appear
to be a set of SQL tables, so extraction of useful data may be
possible here as well. If I could find documention on performing
'macro' commands on a running OO session from another program I could
use OO to build pdf files from a search application (you can do this
under windows using VB script to control a word session).

The QST view database is somewhat incomplete as the final pages
of an article are not referenced in the database and you have to
manually hunt for them, even if you use the windows software.
QEX mostly kept the articles contiguous.

Have you just started playing with this?

Because someone did write about their experiences years back, at
least I think they had had success with those CDROMs under Linux.
I've been meaning to go digging to try to find the post or posts,
because now that I have a computer with a CDROM drive, obviously
those QSTs on CDROM become tempting. And I've never had Windows
running here.

What LEDs do you use for a display that needs to be readable in
sunlight?Obviously, regular LEDs are too dim. From what I have heard,
the LEDs should be at least 2000 mcds in brightness, have at least a
60-degree viewing
angle, and have clear or diffused lenses.

But for all the sources of LEDs, the >=2000 mcd LEDs have viewing
angles that are no larger than about 20 degrees. I realize that
there will be some trade-off due to energy issues (analogous to
highly directional antennas vs. omnidirectional antennas), but I'd
like to hear your real world experiences.

What do you suggest? Should I trade off viewing angle to get the 2000
mcds? Should I trade off the mcds to get the 60 degree viewing angle?
Do I simply need to look harder and be prepared to pay more?

Perhaps you should think about using an LCD? More involved to drive,
but certainly visible in sunlight!

Hi There,
trying to interface an Adonis AM503g desk mic to a TS120. Anybody got
any ideas ?

Regards

Colin

Uhhh...

Take a walk through the strip in Las Vegas some time, count the LED
billboards. Count the plasma billboards. Count the LCD billboards.
You'll be able to count LCDs on the fingers of one elbow.

Luxeon emitters -- quite expensive, big and brite

Agilent has a whole series of ultra-brights on their website.

Note -- an LED's brightness is inversely related to temperature --

Hi,

I have a spare RF signal generator that has an unmarked output from a
type of socket I've never seen before. What's the simplest way of
establishing its output impedance? I've had a few ideas but no doubt
someone out there will know of something better, since I always seem
to end up making unnecessary work for myself.
Any suggestions?

I've been looking at this for awhile, but havn't yet written
any code. Havn't yet figured out which SQL database to use,
but there is an embedded open source implementation (name escapes
me at the moment) that is easier to use then MySql or Postgres

which doesn't require the server to be installed. Converting
the QST view database would require a simple C program to read
and parse the ascii file into three tables, then just write
some simple SQL searches to retrieve the data.
The hard part is to access OO write via backdoor scripts to
create a document to read or print from the images on the cdrom.
Of course that part can be done by hand once you have the list
of file names.
I hope to find time to sit down and write the code to do the
first part, maybe someone familar with the backends of OO can
help me with the second part.

I have had one for several years. There is not much to it. Just be sure to remove the "shipping and storage" wire from the back of the meter if it is there before using it. It is a piece of springey bare wire across the meter terminals. It may not be on your meter. Very nice meter but the meter is very much dampened. It will take a while for it to reach the maximum value. Just pop in the slug that you need for the range and power level. It is the meter that has a SWR adjustment knob on it you turn it to the neasuerment jposition and find a range where it is off scale, then adjust to full scale and then turn the slug 180 deg to get the SWR. Or you could find a chart the Bird meter uses and get the swr off the chart for the ammount of forward and reverse power.

There certainly are led's bright enough to see in daylight. Many of the
new traffic signals actually use leds! Not to mention the brake lights
on many trucks. But these are clusters of smaller leds packed into a
tight bundle and housed in reflector.

Paul,
The most obvious method would be to measure the open-circuit RF output voltage, and then measure the output voltage with a known load. The output impedance is a simple calculation of the ratio of the voltages.
However, depending on the vintage and quality of the generator, the impedance is likely to change with frequency, and possibly even with output level. For source-impedance-sensitive measurements, it's generally a good idea to put a small amount of fixed resistive attenuation at the output (6-10 dB) in order to "fix" the impedance.

The application is an SWR/wattmeter for amateur radio. An LCD would
not be suitable because the power level fluctuates many times per
second during voice transmissions (AM or SSB modes). This would
render the numeric readout useless. True, there are ways to smooth
out the fluctuations, but that would make the SWR/wattmeter less
responsive. On the other hand, an LED display in dot mode would
simply appear to be in bar graph mode during these voice
transmissions.

It's not such a worry. I have SMD leds from chicago miniature, in a product
with light pipes, that are quite visible outdoors in full sun.

Load it with 50 Ohms, and measure output voltage, remove load and measure
again.
If it is half, it is 50, else do the math.

As Tim said, do think about a different (reflective) technology.
If you're stuck on LEDs, recess them into a black substrate.

Would it be a car-type output socket (deep recessed centre pin)? Would it be an old Advance generator with the rounded corners? If so, it's almost certainly 75R.

>What's the simplest way of establishing its output impedance? I've had

If it has a resistive output attenuator with no DC blocking capacitor, you can switch to maximum attenuation (minimum output) and measure Zout with an ohm-meter.

The newer ARRL Periodicals CDs are all PDF files. There is one PDF per issue so it's pretty handy compared to a tiff file per page. I stuffed it into my Fedora box an read it with no problem.

The generators are more of a voltage source. They will deliver their rated output when loaded to the proper impedance. Load it with 50 ohms and see if it gives the rated output. If not try 70 ohms, or another value. One of the reasons for using a 6 db pad is that it helps isolate the impedance of the generator and receiver.

Depends on the size you are looking at. Yes, the large sizes can be
expensive.

The syringe sizes (35 g) are about what I pay for a 1 lb roll of solder
and are the only sizes that I purchase for small projects (less waste)
http://www.wassco.com/kessolsn.html

R276 No-Clean, 35g WAS-01-021403$12.95
R500 Water Soluble, 35g WAS-01-021603$12.95

Refrigerator - that's how I bought it at the Acitve Electronics stores in
US, before they closed.
I was also told they did not keep solder paste more than 2 to 3 months at
each store.

Store in a refrigerator away from your normal late night consumables .....
or that pasty taste in your mouth might be the last tube for your project.

Well, mine apparently has a little problem. The knob on top, which lets you select the power level, that knob turns a cam which raises or lowers the sensing element. Very nifty mechanism.
Now in my meter the shaft which holds the know spins in the cam and so obviously nothing happens. So I took the hole thing apart and fixed that problem and in the process you wish you had the description or maintenance instructions which would give you the exact distance of the sensing element for each power range etc.

So thats why I was asking.
And the thing is built beautifully, thats for sure, I just seem to have to recalibrate mine.
Maybe somebody else here has some documentation for the device.

Without doing a conjugate match and accounting for the impedance of
the voltmeter and the load, the best he'll be able to do is _assume_
that what he measures is what he's really got.

Those CD's are the ones for a single year. AFAIK they have always been
pdf format. The multi year cd's are of the tiff/jpg image kind, with
a windows search engine.

> Maybe somebody else here has some documentation for the device.

Here is a scan of the procedure. YOu have to hook up a 50 ohm dummy load
and a known accurate meter after the urm120. That is the test setup referred
to as fig. 6. There is no exect distance, just turn the screw tuil
calibrated against a known standard.

ET61O-AA-OMI-O1O/81':1 SE502

NOTE

A precision RF Wattineter or a Calorimeter of the desired
accuracy may be
substituted for Items d, e and f.

6-12. PROCEDURE. Perform the following steps to calibrate a
coupler-detector
assembly:

1. Connect the test setup shown in figure 6-1.

2. Rotate the knurled slide knob on the coupler-detector assembly so
that the
arrow on the power selection plate points toward the 50-ohm
termination load.

3. Position the power range knob on the coupler-detector assembly to
the power
range within which the calibration is to be made.

4. Remove the two screws (9, figure 7-2) that secure the power selection plate
(10) to the slide knob assembly (12) , and lift the power selection plate (10)
over the power range knob (7).

S. Apply power to the RF power source, making certain that the RI' source is
operating within the frequency range of the coupler-detector assembly.

6. Compare the reading of the wattmeter with the reading on the test eguipsent
power meter, taking into account the coupling factor of the directional
coupler at the frequency being used.

Rotate the power range knob approximately 15' from its normal position in
order to line up the hole in the slide knob assembly (12, figure 7-2) with
the hole in the slide cam assembly (13). At each setting of the power range
knob the hole in the slide knob assembly (12) is directly in line with the
arrow on the power range knob.

Insert a 1/8-inch hexagonal (Allen) wrench through the holes until the
tuning knob lines up as indicated in Step 7, into the socket of the
calibrating screw (11).

Turn the calibrating screw (11) clockwise if the power reading of the
wattmeter is higher than the test equipment power mater, counterclockwise
if lower.

NOTE

If the correct reading can not be obtained within a half turn 0f the
calibrating screw, the diode must be replaced.

Reasemble the coupler-detector assembly.

3483. DAB Receiver.

I have seen some DRM projects on the net, but none about how to homebrew
a FM/DAB receiver.
Is it such difficult to design and build one of them ?.
DAB receivers are now generally available in commercial form, so I think
there is also room for experimenters.

Andrew.

I expect amplitudes to double or at least rise, after
removing a load. Just nitpicking ;)

well i have just made 12 boards holding 100 or so 0805, 223, 20sm dil.etc..
it took a day..
in the end i got out very small twezzers placed the components on board held
in place by small drop of super glue dispensed by end of tooth pick, and
held down by other end of pick till dry....
then soldered using small iron...
all worked first go...

BUT.. my eyes didn't half hurt by the end...

there must be a better way..ez-bake i dont think is it..any other ideas??

how is it done professionally..???

Take a walk through the electronics department of your local store.
Count the LED calculators. Count the plasma calculators. Count the LCD
calculators.

Maybe I'm wrong but I thought the OP was talking about handheld, battery
powered equipment.

If he's building stoplights, yes LED's are the right choice.

Yes - sentence construction could have been more clear,
it should have been inferred as 'If it is half *before you removed it*
now that would be wrong too, 'If it WAS half' OK.
No, actually it was correct, cause 'it' referred to the first measurement.
Did you collect many nits while picking ;-)?

Hello Paul,
what is the brand name and model number of your RF signal generator.
Can you descibe the socket to us.
Regards,
John Crighton

>But for all the sources of LEDs, the >=2000 mcd LEDs have viewing
>angles that are no larger than about 20 degrees.

30 degree ~5,000 mcd (at 20 mA) and 45 degree 2,000-3,000 mcd (at 20 mA)
are now available in orangish red, reddish orange, green and white.

60 degrees is less common for high brightness LEDs and usually made with a
diffused package, but should be able to exceed 1,000 mcd.

There are rectangular flat-tip packages with a nominal viewing angle of
100-120 degrees and those get around 500 mcd, maybe somewhat more
nowadays (at least for green and white).

> a FM/DAB receiver.
> Is it such difficult to design and build one of them ?.
> DAB receivers are now generally available in commercial form, so I think
> there is also room for experimenters.

A discrete-component DAB receiver is not a project to be undertaken lightly. On the other hand here in the UK, DAB receivers are now very common in the stores due I believe to an outbreak of chip-sets by such luminaries as Philips.

So Google for Philips/SAA3500/PDF and you should get a feeling for what is involved.

Cheers - Joe

Thanks John (and others).

The model number ain't gonna mean a lot to anyone as this is a very
old piece of kit (1950s) that I keep mainly out of a sense of
reverence for the past. :-) It's an old ex-RAF AVO. I have posted a
picture of the socket to a.b.s.e under this same thread title...
BTW, there's a 5p coin shown for scale, but since that won't mean much
to anyone outside Britain, the outer of the socket is approx. 1" in
diameter (which won't mean much to anyone in europe but it serves them
right for adopting the metric system.:-))

Or double, presumably. :-)
Well there you go; I knew there must be a more elegant solution to the
one I dreamed up which basically involved taking a spread of 10 carbon
resistors of from 10 - 1000 ohms and measuring the applied voltage
across each, then arriving at power transferred in each by V^2/R;
drawing a graph of the results and finding the point of maximum power
delivered.

Source record: 26433

Iï¿½m posting this just on the Boat Anchors, Homebrew and Antique radio-phono newsgroups.

Last month at a garage sale ï¿½ I came across a large stack of Popular Electronics and other electronic magazines from the 50ï¿½s 60ï¿½s and 70ï¿½s that were about to be thrown away.

Reading them has been a hoot! Unfortunately, I donï¿½t have the space to store them but I still would like to keep reading them.

So, I plan to scan them by month on CD.

One month = One CD.

I will scan them in both Mac PICT format and Windows BMP format with no compression. Most scanned images like QST CDï¿½s are in TIFF or JPEG format which usually pretty bad for scanned paper.

Yes BMP and PICT take a bit more data ï¿½ but with a 600 Meg CD, I should be able to get an entire month with room to spare.

I have written a very nice program to view PICT files for the Mac. I write my programs in SmallTalk which is object oriented so I can use the same objects and come up with a WINDOWS BMP version. It wonï¿½t be easy but it could be done.

The question isï¿½ would anyone like a copy?

The idea would be to send out the current month and keep things interesting by choosing various years and sending it out once a month.

Like 1956 for June and 1966 for July and so on.

I plan to scan them cover to cover and keep all the ads, (which is part of the fun). To get perfect scans, I will have to destroy the binding and carefully take apart each page to be scanned.

Itï¿½ll be a lot of work.

I figure $3 per CD will cover the cost and postage.

No subscriptions, no eBay auctions, This offer is only for these three newsgroups.

I am looking for opinions or interest only - no orders at this time ï¿½

Please email me.

If no one is interested ï¿½ Iï¿½ll only scan it in Mac format and keep them to myself.

There will also be an upper limit ï¿½ I donï¿½tï¿½ want to spend most of the day burning CDï¿½s.

This is just for a few folks wanting to re-live the good old days in electronics before computers and "outsourcing American jobs to communist or socialist nations".

> WTF is a "6dB pad"?
> --

A pad is usually 3 resistors in a small container. They can be a T or a Pi type. This is the way the resistors are configured in the pad. You may also see them referred to as an attenuator. The number 6 db is how much the pad reduces the signal in power. You can get them from about .5 db to 20 db. They have to be used for the impedance they are rated at. They are for reducing the signal level and also to help isolate small differences in impedance.
For the calibration to be accurate on your generator it sounds like the scale is calibrated so you need the 6 db pad after it. A 5 db pad will reduce the power by a factor of 4 or a voltage by a factor of 2.

CMDA5-1 is the part number.
The MCD rating is not spectacular, but they are surprisingly bright, and
quite visible in full summer sun.

I think I might be interrested in some of them. Let us know exactly
what you have. I also have some old pop'tronics mags that I might think
of scanning myself (maybe have some you don't). Also some old
Electronics Illustrated mags. Being a Linux person, I think the bmp
format would be better for me than the PICT format.

If you get over run with requests maybe someone with more time on their
hands could duplicate your CD's for you (second source?). And maybe
someone out there with large BW could post the iso images on the web (a
month at a time for the current cd?).

I'm not sure why the .tiff and .jpg formats are a problem, the QST view
scans don't look too bad, and some of the problem seems to be they
were made from scans of microfilms of poorly stored old magazines!
Pehaps someone with some experience using image software can comment.

Also, less commonly, a device used to match the impedance of a
generator to the impedance of a transmission line or a load, or the
impedance of a transmission line to the impedance of a load.

The impedance of the generator, line, and/or load are assumed to be
purely resistive, and there is always loss associated with the
transformation. Devices which exhibit the least loss are called
"minimum loss pads", and

http://www.maxim-ic.com/appnotes.cfm/appnote_number/972

gives a good description of the process involved in designing one.

The reference given to Bruno Weinschel and the ITT handbook (as we
old-timers call it) is particularly good, and if you're interested in
RF (or just about anything else...) and you can buy a copy of it you
should.

BTW, since a pad is usually rated in terms of the power it's supposed
to lose between its input and its output, the reference to "output
EMF" on your generator may be what it supposed to be with a 3dB pad on
its output.

Easy way to find out would be to build a 3dB and a 6dB pad to find out. For a 50 ohm tee pad, here are the resistor values you'll need for -3dB:

```
0dBIN>--[8.55]-+-[8.55]-->-3dBOUT
|
[141.93]
|
GND>-----------+-----------><GND
```

and for -6dB:

```
0dBIN>--[16.61]-+-[16.61]-->-3dBOUT
|
[66.93]
|
GND>------------+-----------><GND
```

The input goes directly to your generator, (assuming its output impedance is 50+j0 ohms) a 50 ohm resistor gets connected across the output of the pad, and you'll measure the voltage across the 50 ohm resistor.

Use non-inductive resistors (carbon comp if you can get them) and keep the leads short. That is, ********KEEP THE LEADS SHORT*********.

Biz,

Why don't you just scan one each month and have the file available for download someplace for a period of time. That way we can pick and choose the months that interest us and won't have any need for intermediate media or the costs of same?

<< I will scan them in both Mac PICT format and Windows BMP format with no compression. Most scanned images like QST CD1s are in TIFF or JPEG format which usually pretty bad for scanned paper. >>

Biz-

The reason you don't like the TIFF or JPEG scans, is because they are bad scans! If done at a high enough resolution, TIFF is close to the best you can do. JPEG compresses the images to reduce file size, but will degrade them if you go too far.

Although I am using a Macintosh, I think you are wasting your time with PICT and BMP formats. I would recommend scanning to TIFF and converting to JPEG for the final product, unless you can fit both TIFF and a good JPEG on one CD. If your scans have good detail, there may be more data than you expect.

A format that may work with the widest selection of systems, is Adobe Acrobat PDF. That may be the best way to consolidate all of an issue's pages into a single document. Many of the equipment manuals on the net are in that format, and some have extremely fine detail.

==========
Since Britain is part of Europe you probably mean 'anyone in continental
europe'

Just for your info ,the metric system was introduced /imposed by Napoleon
(eg more than 200 years ago)
For once he did the right thing ;) .

Those ex-military AVO's were really nice g.p. signal generators though could never afford one. Seem to remember they were 50ohms out. The o/p socket and plug were standard 50's military chic and still available.

Go on, tell us the model number, there are a lot of us
still interested in boat anchor style test equipment.

Is this unit similar to your sig gen
http://www.thevalvepage.com/testeq/avo/sg3/sg3.htm
http://www.thevalvepage.com/testeq/testeq.htm
Unfotunately the connector has been removed and a
BNC type fitted.

I am guessing that you want to keep the original connector
on the sig gen and find a matching connector to make a
short test lead. Old Style connector to BNC.
My news group service doesn't allow me to see the group
a.b.s.e Pity. So I can not see the picture you posted.

So, what are the results of connecting your ohm meter
to the RF out put connector (with the unit switched off)
and measuring the resistance on all attenuator positions.

On one of the lower frequency ranges when you connect
up your cro via a "T" piece to the sig gen with say a 75
ohm load. Does the output level jump up to double
when the load is removed?

Repeat the experiment with a 50 ohm load. If the voltage
doubles from loaded to no load, you will be laughing.
But I don't think you will be that lucky.

I am guessing it will be closer to 75 ohm output impedance.

Try different value loads and let us know how you got on.

Cheerio,
John Crighton

Message-ID: <4095DF4C.168A6AF0@rickfrazier.com>
Source record: 26247

As at least one other replied, I would also be interested in some of them, but don't have the budget for all.... It would be an interesting trip down memory lane, having lived it once, but would like to have copies of some of the ones that have interest to me, particularly things that interested me back then....

I'd agree with the PDF as a good candidate for output format. It usually looks good, and even the linux guys probably have a PDF viewer by now.

Depending on the actual size they end up, there might be some possibility of putting them up on a web site. I've got a couple of sites that have about 500mb free each, and might be convinced to host something if the terms were right. (if they were reasonably popular, maybe you could post a couple of issues a month, with paid download for those interested... I have set up this sort of thing before so have most of the code already here on my development system. Of course, for a paid download, the price would need to be less than $3 per issues...). Anyway, I know there's extra bandwidth and storage space out there in the Ham community if there is interesting stuff that needs to be available on line, even if for a relatively short time.

Thanks

Not really similar to any of them, I'm afraid. Model number is CT
378B. I did recognise that old Advance E2, though. Had one of 'em
about 25 years ago. It was pretty ancient then!

>I am guessing that you want to keep the original connector

Pity. Hopefully some kind soul will post it onto a web site for you. I
can't as I have no FTP s/ware installed at present. :-(
The output is just under an inch in diameter and is co-axial as you
might expect. The centre pin is about 1/16th" thick and doesn't
protrude beyond the outer. It's pretty unremarkable apart from its
size; much larger than one usually sees.

Yup, John Chrighton's another one that springs to mind as being very
good at sniffing stuff out on the Web.

I'd often wondered what these "pads" were for. I'd been a bit
concerned to note that the output amplitude varied quite markedly when
sweeping the generator through it's frequency range when measuring the
'open circuit' voltage with a 'scope. I guess now I know why.
Thanks, guys.

Yes... but actually that's not where your thinking and mine diverged.
I'm not sure why, but I was thinking of transmissive LCDs (i.e.
backlit color TFTs and STNs), which by and large are totally
unreadable in sunlight.

One more thing to keep in mind, Paul. Over here in the US it is and has for a long time been standard to display the LOAD level on the generator output indicator. That is, the voltage (or power) at the load itself (assuming matched). In the UK - but I don't know about recently, it was common to show the generator EMF -- which meant the internal generator voltage. This would be twice what would appear across the load if the load & source Z were equal.

From your Sig you may very well be familiar with the EMF designation...

Oh yeah. I forgot about that!
Better ask here first though, as it's a binary and might not be
welcome.
I've also taken a shot of the whole gen., John. I can certainly e-mail
the pics to you if you're that interested in boat anchors (although
this one's only 25lbs so hardly qualifies). My Marconi, OTOH, has got
to be 3 times that much at least...

3533. Spectrum Analyzer - VCO Results

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-03 18:19:42 UTC
From: Alex Collins <me@privacy.net>
Message-ID: <c762dk$5is3$1@ID-180264.news.uni-berlin.de>
Source record: 26257

I've tried benching up a Minicircuits POS-900W VCO module.

With a Spectrum Analyzer (RBW 1 kHz, VBW 1kHz, peak hold, 100kHz span) I've been hoping to see a clean waveform that drops to -75dBc at 1,000Hz away, as specified in the Minicircuits spec. Instead, I have something that looks like a triangle spreading for MHz!

I've got in such a mess, my brain is now totally confused (not difficult!). I just don't understand why the trace doesn't look good, compared to my own discrete design(lower frequency) VCOs. Even with the POS-900W out of circuit (ie. no PLL), well grounded, and run from batteries, the waveform is still more-or-less a triangle!

What could I be doing wrong? (My other POS-900W's do the same).
Incidenatlly, I have a screenshot (23Kb) of the display which I can e-mail.

Well, you don't specify the frequency coverage of your other VCO's, MCL's
have a very high MHz/volt tuning rate and unless the tuning voltage is
absolutely quiet, they'll look pretty bad. (BOTH the positive AND the
negative leads shielded to ground?)

Thank you for the reply.

But surely if the Minicircuits datasheet says the trace will fall to less
than -75dBC at 1,000Hz away I should see that, or something close to it?
Irrespective of the frequency (800MHz)?

Even if the conections aren't ideal, I'd expect 10dB or so more noise, but
it doesn't change however good/bad it's shielded.

I'm probably doing something really stupid.

Al.

Well, Harold is pointing out that noise on the tuning line will
show up as broad phase noise. What are you using to drive the
tuning voltage line?

The old Ramsey FX440 UHF transceiver had a horrific noise floor on the
transmitted audio, since the VCO had about 10MHz/volt sensitivity and
the audio modulation was fed from an ordinary op-amp into the tuning
line. You could be seeing a very similar problem.

Dana

I have a radio from Tandy Aerospace in my truck. It's an otherwise
cheap piece of crap (the radio, the radio), but it _does_ have an
always-on LCD clock that's reflective when the truck's off and backlit
when the truck's on. Very nice. Doesn't make up for the sound when
it's turned on, though...

Hello Paul,
Yes, I would be interested to see the pictures of the AVO CT378B
What was the Marconi sig gen model number? I missed it.
No need for pictures of the Marconi unit. I might know it from
the model number.
Regards,
John Crighton

Hi All,

Does anybody have a list of the RF projects that appeared in Radio & Electronics World (UK magazines from 1981)? - Many projects found themselves as kits by Cirkit. I would like to buy some back issues for nostalgia but there are some 4 years worth !

Many Thanks

John Silver MSc MIEE CEng

3544. Re: Ameco AC-1 revived

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-03 22:51:39 UTC
From: Uwe <outhouse@midcoast.com>
Message-ID: <BCBC453A.5C53%outhouse@midcoast.com>
Source record: 26267

Ok Folks, at the end of a long saga of fiddling with an old technology tube transmitter is this bit of satifying news:

A few days ago, I had a QSO with a fellow in Ohio, I received an email and mp3 sound file from a fellow in Leeds, England, who had heard and recorded my little 5 Watt signal and this way I could hear it too.

He gave it a 429-539 QSB and listening to it I was embarrassed by the less than perfect code as well as the detectable chirp but oh well...

So now is the time to start the construction of that more advanced version of a starter transmitter using two 807 as finals, who was mentioning that design way back??

Anyways, hints of where to find the circuit diagram are welcome.

With a very chirpy 73

Uwe

Okay, John. The Marconi's a TF 2002AS. I'll post you a pic of the AVO
2morrow as I'm a bit shagged-out right now (bank holiday boozing here
2day).

See if you can get a copy of the ARRL Handbook from the '40s or '50s.
'60s will get you some 807's, some 1625's (still cheaper than 807's at
Antique Electronics Supply!), and some 6146's.

The metric system also the law here in the UK. You can't sell stuff in
pounds and ounces or feet and inches. Miles are the last bastion of
the imperial system (on road signs), with the informal exception of
pints of beer (IIRC technically it's a "large" beer and 576ml). I
don't mind working in metric units, indeed I prefer them, but if
anyone wants to stop me asking for a pint in the pub they'll have a
fight on their hands!

Oh yes, cannabis is still sold by the fraction of an ounce as it ever
was, but I don't think selling cannabis in imperial units is any more
illegal than just selling cannabis :)

Source record: 26272

I'm not terribly familiar with the MiniCircuits VCOs, but I have been involved with getting the phase noise down to low values on some of our designs. I can tell you that it's important to have power supplies be very clean, as well as to have the control voltage very clean (down into the microvolt region or below) as Harold says.

But from what you wrote, I gather there's a problem even with things supposedly very clean. BTW, I don't 'zactly understand the "POS-900W out of circuit
(ie. no PLL)" bit. What are you measuring if the oscillator is out of the circuit? Or are you saying you're measuring the oscillator "bare" and not in a feedback loop?

Do you have any other signal you can measure in the same frequency range? Is your spectrum analyzer up to the task? I'd think your 1kHz res bandwidth is pretty big to be seeing the noise level at 1kHz offset...I'd want a res bandwidth at most 1/10th the offset. And it might be interesting to look with much lower res bandwidth if you can, to see if there is a particular structure to the sidebands, or if they are indeed random noise.

Cheers,
Tom

Source record: 26274

My experience with Minicircuits is that they have EXTREME sensitivity to the AFC line. I'd use a resistor divider from the same battery and a bypass cap.

Something like a pair of 100K resistors and a 10 uF cap. Naturallly, ground the cap at the oscillator ground pin.

Also, the Vcc has to be well bypassed AT THE OSCILLATOR.

These things are very sensitive to any change in the VCC voltage. A battery is often not all that low of an impedance and so some good bypassing will help.

Finally, how are you taking the signal off to your analyzer?

I haven't used the POS-900 but in general, these critters want a paasive 50 ohm attenuator right on their output to avoid signals sneaking back and screwing up the oscillator.

Yes, I know that unit, I have a 2001
Repairing that unit is not dead easy for hobbyists.

I am assuming that AVO at Dover were useless with your
enquiries regarding information on the AVO CT378B

If you wanted a good back up signal generator,
that is dead easy to repair. Here is one for sale.
Marconi TF 144H 50 ohms output Z. BNC connector.
10KHz to 72MHz
http://cgi.ebay.co.uk/ws/eBayISAPI.dll?ViewItem&category=40004&item=3094746090&rd=1

I like that model, for a number of reasons.
Very stable frequency wise (when warmed up).
It has that nice smell inside that you get from valve gear. LOL
Everything inside is getatable.
Big knobs and easy to read dials, good for failing eyesight.
When the attenuator gets smoked by accidentally pressing a
microphone push to talk button of a transceiver under repair
on the bench, it is very easy to replace the resistors in the
attenuator.
It was not that heavy that I couldn't hump it up the gangways
of ships, decades ago, to do radio service work but it is way too
heavy for me now. Heh heh heh...

You might like to check out how far away that unit for auction,
is away from you. I wouldn't pay any more than 45 quid.
Even 25 quid is right on the limit for me. But if no one bids
you could get lucky. I bought one here in Australia for $10
at a Ham fest.

I only mentioned the TF144H incase you were looking for a
good cheap sig gen to accompany your TF2002AS do some
serious radio receiver work. Both have good attenuators.
Having two good signal generators would help you out with
all that filter and interference work that has been plaguing you
over recent months. One sig gen as the desired signal, the
second sig-gen as the interfering signal etc.

Regards,
John Crighton

OK, I built a small 4 digit score board for use outside, and I used LEDS
I salvaged from clusters I bought on E-Bay. The clusters were red/green
mix, and the red ones really are bright in sunlight. Oddly enough the
guy e-mailed me recently to say he had more of 'em for sale.

Here's the web addy he gave me;

http://www.evaluecomp.com
(The clusters are on page 5 of the LED list)

It takes a fair amount of effort to get the leds out of the clusters. I
just cut the case off, and used a blow torch and heated the base until
the solder got hot enough to pull the pcb off the back, then I just
broke apart the expoxy or glue or whatever and retrieved the leds. I had
about 93% success rate, with the other 7% damaged or failed after they
were removed.

Works nice, even at the beach, but the green ones can be hard to see
sometimes.

> design way back??

You almost have to put those 807s in push-pull, for aesthetic reasons. That is easier to do with plug-in coils than with a bandswitch. Then you need a dual variable to tune the dual coils. Swinging link to adjust coupling to the antenna. This stuff shows up at hamfests sometimes. You may find someone's old homebrew rig for sale and you can salvage the parts from it. The Handbooks Tim mentioned will have all the info you need. I started out with a 1953 Handbook but I can't remember what projects were in it anymore. They're all over eBay, don't pay too much. Tim's also right about the 1625 tubes. They're the same as 807s except for the filament voltage and socket.

My second transmitter (the first was a single 6V6) used an 807W, a compact version of the full-size bottle, as the PA. I used a Calumet baking soda can for a shield.

While you're cruising the hamfests, look for an RCA Transmitting Tube manual, a small paperback. They're fun to read and there's some application info in them, as well as the usual datasheets.

I used to use a mercury-wetted relay to key my tube rigs. They're really fast and make a nice ticking sound when you're keying. They also isolate you from the keyed voltage and allow the use of most modern keyers. Definitely in keeping with the period, too. They look like octal vacuum tubes with metal bulbs but they're shiny, not black. 24 VDC is a common coil voltage.

Do you hang out on the boatanchors group? You might be able to turn up some parts and lots of info over there.

(Note that I have quit trying to convert you to solid-state! You are obviously a lost cause. :> Have fun.)

I've also observed.....it you are not using the auto mode on your spectrum analyzer, meaning if you have too fast of a sweep rate for your I.F. bandwidth, you will see the results that you are running into. I use an HP 8558B, and if I set the SA improperly, I will see the same results. Try slowing down the sweep rate if you haven't done so.

No, he cannot. Copying the manual without buying it is copyright infringement, essentially the theft of information from its owner. Renting a manual with the intent to steal the information is mail fraud, a federal offense.

I know this is not a popular stance, but if we're gonna convince the public to treat us as good citizens deserving of our bandwidth, we need to at least act the part.

The Eternal Squire

P.S. Good gosh, isn't poverty expensive?

Sounds like a great idea, actually. The problem is of course that even here we're hardly spoiled for choice IRO older test equipment. Finding one of those particular models for sale in this country would be tricky, I'd imagine. Anyway, I'm about to mail you a pic of the AVO, so keep an eye open in your inbox and don't delete me as spam! Admire those classic 1950s lines.....

Quite a lot of low power toobz are happy to run at 110V plate voltage
(DC of course). The great thing about that happy voltage range of say
80-150V is that you can check for the present of the voltage just by
sticking your fingers between anode and deck. I know I'll get a lot of
abuse for suggesting this, but it works for me!

Disclaimer: Er, but don't try it at home; YMMV; fatalities can occur
at much lower voltages... :-)

WHAT! YOU ARE KIDDING ME!
ARE YOU STILL ON THE PISS?
It is a bleeding Marconi. I thought they were made in
Chelmsford. That is just up the street from where you
are in London, by Australian standards of distance.

The unit I have been going on about is for sale in Beds UK.
Where is that? Bedfordshire maybe. Four streets away
by Australian distances. Current bid 0 bids. 25 quid.
You didn't even look. Cripes.....tearing hair out.
C'mon Paul, sober up.
Regards,
John Crighton
Sydney

Whoa! Calm down there, John. I'm simply not taking the risk of doing
anything Interenet-Explorer related until I've got the patch for the
sasser worm that's flying around the world at record speed. Sure I'll
follow your link as soon as it's safe to do so. Gimme a break will ya?
;-)
BTW, I've just posted you the photo of the Sig gen. Took a bit longer
than I meant to as I've been faffing about with photo software trying
to enhance the image. Taking flash photos of shiny, black objects is
pretty tricky, I've discovered...

In my college days, I spent a couple of summers working with electricians.
One old guy would test for power with the back of his hand. He could tell
the difference between 110V and 220V. He got onto a 440V circuit once and
complained for a week.

Perhaps that's -75dBc at a bandwidth of 0.001Hz?

3564. Iambic keyer with MSP430 chip??

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-04 15:53:00 UTC
From: kc0atc@qsl.net
Message-ID: <a444e1b1.0405040753.5643aa88@posting.google.com>
Source record: 26285

I've seen a number of implementations of iambic
morse code keyers using the PIC chips.

Has anyone done it yet using the MSP430?

Chris

I want to build the "continuously variable audio filter" that's been in the Handbook recently but it seems the main chip, the Maxim MAX295 is out of production.
Does anybody know of a source for these or an easy substitution? Thanks.

> the Spectrum Analyzer on the same settings). But, instead, it's more like a
> triangle than a needle, and nothing seems to change that.

You're subtracting 30 dB (i.e., 10*log10(RBW)) to account for the 1-khz RBW, right?

Also, to look at noise at a 1 kHz offset, you need a much narrower RBW filter. Looking at 1 kHz from the carrier through a 1 kHz filter, you will be only -6 dB down (or -3, depending on how your analyzer specifies its RBW) with a perfect signal! Take a look at the parameters in the graphs at http://www.qsl.net/ke5fx/synth.html -- I use a 100 Hz RBW filter to make measurements at 1 kHz from the carrier.

Also, what other VCOs are you comparing to? A rule of thumb is that equivalent-quality VCOs tend to get about 6 dB noisier per octave of frequency. A very good 900-MHz VCO will have about the same noise profile as a crappy 90-MHz VCO.... and that's without even getting into the tuning-sensitivity question that others have raised.

Finally, simple temperature-related drift (both short term and long term) will make it tough to measure anything 1 kHz from the carrier of a 900 MHz VCO. You're expecting almost one part per million stability from an unlocked VCO, and that isn't reasonable. To characterize phase noise at 1 kHz from the carrier, you should:

1) Lock the VCO with a PLL whose loop bandwidth is at least an order of magnitude lower (100 Hz or less)

2) Use an analyzer RBW at least an order of magnitude lower (100 Hz or less)

3) Perform this test only with a stabilized analyzer (otherwise, its internal LO's noise performance may be even worse than the VCO under test... something that's especially likely with lower-frequency VCOs)

4) Don't forget the 10*log10(RBW) adjustment factor.

Those four steps will get you close, but to do the job right, you need two more:

5) Distinguish between AM and PM noise by using the VCO under test to drive a mixer's LO port to saturation, with a significantly-cleaner reference driving the other port of the mixer

6) Compensate for the noise-equivalent bandwidth of your analyzer's RBW filters. Typically this will make the true noise values 2-3 dB worse than the observed values.

All 6 of these steps may be necessary to reproduce Mini-Circuits' catalog specification for the VCO.

You're probably safe doing anything that works. I'd start by scaling
the caps from an app note, or choose 100 ohms at the target frequency.

Actually you can use an old transistor radio if can. Connect the
primary of the coil up as the tuned circuit and hook the collect tap
of the coil up instead of using a capacitive divider. IE: use a Hartley
oscillator circuit. You can connect the tap using a .001 cap to avoid a
dc connection.

Hello Paul,
I received the picture, thanks.
Those connectors are still easy to come by.
Here is a picture of a different sig gen but with a similar
style connector to yours.
http://www.thevalvepage.com/testeq/triplet/1632/1632.htm
That connector is a Pye connector.

Your connector is very similar but just slightly different.
When you contact AVO at Dover, ask them the name
of the RF connector that was used. Telling them it is
similar to a Pye should jog their memories.

If you are a purist
and you want to keep the original RF output connector then
you can find some at Ham radio trash and treasure field days
or if you are in a hurry, check out some radio service workshops,
like taxi two-way radio repair joints. Most technicians are horders
of old stuff. They might have an old lead with connector.

If you are not a purist
in keeping old gear original but only functional, open the unit
up and see if the old fashioned RF output connector can be
replaced with a BNC connector easily.

You still haven't told me what ohm meter readings you got
when you placed the meter prods from inner to outer on the
RF connector. (sig gen switched off)
Flick the attenuator switches to all positions. You are looking
for fairly consistent readings to check if the attenuator has
been damaged by a transceiver that transmitted accidentally
or the attenuator having being connected to a high DC voltage.

Tell us. Were the readings close to 50, 75 ohms or what?

Here in Sydney the Wireless Institute of Australia, a kind
of head office for hams keeps old manuals and circuits.
There would be an equivalent office for UK hams in London
with a library of old manuals for sure. Some UK hams
on this group will tell you who to contact.

You can still get those RF connectors and if you try hard
you will find a manual for the AVO CT378B.
Do the obvious first, phone or e-mail AVO.

"The Megger office in Dover
Archcliffe Road, Dover, Kent, CT17 9EN, England."
http://www.avointl.com/common/images/DoverMap.gif
The phone number is on this map.

There you are, they are a couple of hours down the road
from you. Nearly next door. Call in with your sig gen and
ask for a photo copy of the circuit, they will probably chuck
all sorts of stuff at you. :-)

Regards,
John Crighton
Sydney

They are pretty much the same thing. The 612 has looser specs.
I suspect for anything where it can be used, it wouldn't matter too much
which one you choose.

Keep in mind that it's not necessarily the best choice for a mixer
with strong signal handling capabilities, it was afterall originally
intended as a second mixer after filtering, but that shouldn't come
into play between the 602 and the 612.

Certainly looks like the one shown, I must say. I'd always thought Pye
connectors, though, had three pins, like the one in the photo I sent
you in the top LH corner. Or maybe that's a Bulgin connector. Blimey.

Okay, John, just out of curiosity I will. I expect them to tell me to
get f*cked, like HP or Tek would, but we'll see what their "extended
aftersales care" is like. "What do you mean I ought to be a new model?
This one's only 50 years old!" :-)

I'll post the results later today, along with answering your other
queries.

Yep, that's a good question for Win.

Suitable general purpose MOSFETs for RF finals (probably only feasible in the
shortwave range) and best way to drive them.

Let's say the more power the better (10-200W).

If you are going to use your dipole for any bands other than 80 meters, ladderline is vastly more efficient. I would definitely NOT coil the ladderline. Been there done that...didn't work for me. What are you tuning your ladderline with? I just built the Richard Measures' Balanced Balanced Tuner for mine and it works great. The article is on the ARRL website.

Paul,
assuming that I understand your question and assuming you want a
50ohm-50ohm HF amplifier for CW, I have seen several designs using an
IRF510 MOSFET for amplifiers up to 30 MHz.
On a QST article using 2 IRF510 in a push-pull fashion some 30W could be
achieved over the entire HF range. For a simpler design check the NB6M
Miniboots (http://www.amqrp.org/kits/miniboots/miniboot.htm).

To my understanding, switching MOSFETs can be used as HF C-class
amplifiers as long as their gate capacitance is low (few pF).

As an example, IRF530 has a way too high gate capacitance to allow
acceptable HF results. On 80m it might be good, thought.

HTH,
Paolo IK1ZYW

Excuse me???

I recently bought a surplus HP54659B module for my HP54602B DSO and had trouble getting it to work, so I called Agilent for help and, even though the scope and the module are no longer supported by Agilent, they took the call, assigned me a case number and a pleasant technician, and when she couldn't come up with a solution while we were on the phone, went away to try to find some information she needed to work on the problem. All for free. Above and beyond, I'd say...

In the meantime, I continued to try to solve the problem and found it was pilot error, so I called them back to let them know and to thank them for their time. I also found out that even though one of their instruments may become obsolete or break, they'll still do fee-based repair and cal.

I hope you fare as well with Marconi.

Okay, I've just phoned them and drew the anticipated blank, I'm
afraid. It appears all the old info; manuals, spec sheets, data etc.
on all obsolete models got thrown out years ago. They only keep info
on current models, regrettably. Still, at least they didn't try to
sell me a new one.

I think the obvious thing to do from my PoV is just to leave the front
as is for the sake of originality and just put a BNC socket at the
rear and feed the mains power in via a grommeted hole likewise at the
back. Having a dirty great power lead coming into the front panel
would have looked pretty gross anyway.

>If you are not a purist

Hi Old Men

I am looking for a 27 Mhz (in) to 7 Mhz (out) transverter, mostly a kit to transmit in 40 m when I'll be allowed by the french administration.

I don't want to use a multi band trx, just an old CB rig and a transverter in my car from my home to my job place and return back home (one hour a day).

If anybody knows an adress, thanks in advance for the reply.

Yeah, 50 in; 50-75 out say. As for frequency, that's what I'm trying
to establish: the highest useable frequency device for say 50W-100W
out. Amplitude's subservient to power. What kind of frequency upper
limit might be achievable? Say with the best gate driver arrangement
conceivable?

You are aware that there are power RF MOSFETs that go up to VHF, probably higher? There's a number of manufacturers out there -- I know Motorola makes them, probably any one that is in the cellular base station business makes them. You can pretty much build an amp off of a Motorola app note.

As far as using 'regular' power MOSFETs they tend to have very high gate capacitance as a result of getting the Rds down. Since Rds isn't the main efficiency driver in an RF amp the chips aren't well suited to RF application.

I know the ARRL handbook has information on MOSFET amps from 'standard' power MOSFETs, and there have been a few articles in QST and QEX.

I think what we're looking for here is a cheap, garden variety MOSFET used
as RF power amp.

Yep, there are units out there that will do VHF, UHF and maybe even SHF, but
the price will be Ultra High as well :)

Do you want a linear amp (per the subject line) or a class C amp?
They're not the same critter.

There was an article in QEX just one issue ago about a P-P power
MOSFET amplifier for 7MHz.

There are power MOSFETs designed specifically for RF service: just do
a Google search for 'RF power mosfet' and you'll get lots of hits.
Many are designed for service well beyond HF.

Why? It's way less conductive than copper, so unless you're making an
air-wound coil that needs to save a few ounces I can't see how you'd
save anything using Al over Copper.

But I'm willing to be educated.

The truly hardcore would want to implement Eureka-147
themselves. Who needs those silly chipsets anyway? :-)

We have a mostly-functional DAB setup in Canada, using
Eureka-147 (same as you Europeans) on frequencies around
1.45 GHz (not at all like you Europeans). It works
if you live close enough to the transmitter (I bought
one of the little Perstel radios for the hell of it),
but is highly unadvertised.

Technically you're right, of course. I want to make an amp that
operates in Class C - yeah, I know that mode's the antithesis of
linear but over here in Britain, these bolt-on after market boosters -
though running in Class C., are knowns as "linears." I don't
understand it either.
Class C RF amps are basically switching on and off at high speed, so
it seemed like a job better suited to a power FET since power RF BJTs
are pretty expensive. Of course, I can now gather than the same
situation pertains with FETs as well.

>There was an article in QEX just one issue ago about a P-P power
>MOSFET amplifier for 7MHz.

It'd be fun to see just how fast you can force current in and out of
an ordinary, GP power MOS FET gate to get it switching as fast as
possible, I reckon, before pressing ahead with the dedicated devices.

Hi Paul,

Is cost an issue or do you just want to see if it can be done with MOSFETs? About 25 years ago I did a small amp (25 watts or so) above 100MHz with FETs. But I found that cost was much higher as if I'd done it bipolar. When I looked at 100W my then pretty puny budget made the decision for me to go bipolar.

Personally I haven't seen much happening in cost/performance and I'd probably start out bipolar. Another cost saver is if you leave the supply voltage level a wildcard even if this is for a mobile app. It's no big deal these days to create whatever voltage the transistors like best from whatever is there as a supply.

I am still a big fan of tubes, as long as they are popular enough and thus cheap. Transistors are rather fickle and a tiny glitch in the load connection can send them to the greener grass in a millisecond. Tubes brush this off in stride.

For rock bottom bill of materials budget it has always paid off to check what TV manufacturers use in the horizontal deflection finals. That's as low cost as it gets. But I guess with the advent of big plasma screens that may fizzle over the next 10 years.

Regards, Joerg

If I have a waveguide, coax, or even lumped varactor tuned LC tank, could I simply select which harmonic I want it to oscillate at, by tunning a negative resistance?

Perhaps with the use of a "register key", such as is on flutes and clarinets? I suppose that functions as a high-pass filter on the line, when the hole is unplugged.

I'm interested in a multi-decade VCO, tuned with one control voltage and just a few switches.

No, I don't want to heterodyne or synthesize, because I'm interested in the regenerative/super-regenerative capabilities.

Any applicable app notes or articles? Dream on?

From an attenuator a large range is undesirable. The opposite
is what you want.
Lets just call the RF output Z for this unit 75 ohms Nominal. :-)
And you have crappy pots to put up with. Not good.

This unit is a bit cheap in the attenuator department.
Pots for both course and fine controls. I don't like that idea.
I prefer a switched attenuator for course and a pot for fine.
I'd much prefer a switch for fine also but that would be
too expensive.

Do a simple leakage test to see if this particular AVO
sig gen is worth keeping. On the bench beside the signal
generator place a radio and see if you can pick up the
signal from the generator. If a signal roars into the radio
then it is next to useless for serious or even hobby radio
work. Shield the RF output connector or short it.
(attenuator set to minimum output)
If it leaks RF and the frequency drifts a lot then you
might as well forget it.

A friend of mine did have a good use for a few old
crappy signal generators. He was into restoring really
old radio sets, record players with big horns and pianolas,
those pianos that play by themselves.
He was giving a demonstration of his gear at his house.
In another room he had the old signal generators being
externally modulated by modern tape recorders playing
old 1920's and 30s type music. The visitors were amused
and confused to hear the old style music coming from
the old style radios as they could tune into the local stations
also. The bullshit flew from those in the know. :-)

I suspect that you have a choice between (a) losing more power to
resistive losses because of the lower conductivity of aluminum or (b)
increasing the weight of your power converter because you've increased
the core size to save on resistive losses. You may be able to do better
with _silver_ wire and a smaller core, for all I know.

This doesn't mean that you shouldn't make the attempt, I'm just
wondering if you've taken all the variables into account.

Have you already pushed the switcher frequency up to insane levels?
Looked into resonant topologies, all that stuff?

Aluminum is the lowest weight conductor.
Copper, Silver and Gold have lower drop per unit area, but

Al is the lightest.

12Ga suqare Al has 2.260 ohms per K ft.
Weighs 7.28 lbs per K ft.

14 Ga Cu has 2.239 ohms per Kft
1Kft weighs 14.99lbs

6% more resistance at half the weight.

From the same chart
11 Ga Al has 1,755 ohms and a wt of 9.237

See:

http://www.mwswire.com/square.htm

I can buy wire from these guys' but they have a $100.00 minimum per line item.

Paul

-- snip --

Right. Aluminum has better conductivity per gram than copper. I
understood that even before you original post.

I also know that aluminum also has much _worse_ conductivity per unit
volume. And that the core that you're going to put it on can probably
accept a finite volume of wire. Since 12 gauge wire has about 50% more
area that means that you're only going to be able to put on 2/3 as many
turns, meaning your inductance is going to be about half of what you'd
get with copper wire. Even with a toroidal core you're still left with
about 2/3 your inductance.

That means that you need to go to a bigger core to get your inductance
up. Not only does this mean that you'll be adding a lot of mass, but a
bigger core will require more wire, so when you're done you won't be

getting a 2x savings in wire mass, and you'll more than likely have an inductor that is actually heavier than the copper alternative.

So, to repeat, have you run _all_ the numbers and verified that you'll achieve a savings?

Time to make some letterhead and see if you can get an engineering sample.
Tell them you're planning to publish the circuit or whatever it takes. Put a
phone number in the letter and advise others who may answer the phone to
expect a call from their sales dept inquiring about future quantities. I
don't recommend people do this simply to avoid buying a 2N2222, but it looks
as though you have a legitimate purpose in mind. All you have to lose is a
stamp. Good luck.

Hi,

I'll avoid posting a screen shot of this one since so many people seem to have difficulty finding them on abse or can't get the group at all from their servers.

Imagine a two-state, high/low (on/off) wave form; i.e., negligible rise/fall times. Amplitude 5V. A bit like a square wave, in fact, except that the on and off period appears *different* between one cycle and the next and the next and so on. There's quite a bit of variation (anything from one whole time division to up to seven divs and all times between the two). There does appear to be an eventual series repetition, but it's only noticeable after about 30 cycles. I'm not sure how I've ended up with this, but would it be rich in odd and even order harmonics and suitable for generating them for frequency multiplication purposes, d'you think?

Thanks,
P.

Hi Paul,

Seems like a huge amount of frequency modulation. Or a pulse width modulator? Where did it come from?

abse should be accessible from most servers. But one technique that is easier for people is to upload it to a "scratch pad section" on you web site, a sub domain which most hosting companies let you create. Then you can use a fast FTP tool such as WISE-FTP and zoom it up there, and delete it within seconds once you think it's no longer of interest. This allows you to paste a link right here in your post. Just avoid doing it the cheap way, via one of those "free" web space deals that swamp people with pop-ups.

Back when hexfets first came out (1981 or so), I was having trouble
with them self-destructing. Back then, at least, if you read far
enough in the fine print, you'd find a maximum drain dv/dt rating. I
was seeing close to 100V in about 5nsec just before the
self-destruction as I recall. And the Siliconix V-mos transistors
were good for RF power back in that era.

If you're thinking driving it "digitally", that's probably the wrong
answer. Resonate the input and output capacitances, and life will be
much easier. Charging and discharging capacitance through a resistive
source is quite inefficient. Remember, too, that tuned triode valve
amplifiers are generally neutralized. Be VERY careful to not exceed
the gate-source voltage rating! Have fun playing, but expect some
"surprises."

Cheers,
Tom

And the substrate diode made a nice step-recovery diode, making it
possible to generate lethal dv/dt's in totally non-obvious ways!

John

Mosfets in the MRF5xx series (511, 521 for example) have been used
up to the 10 meter band with good results. A pair of them can give
at least 50w pep output. Depending on the input/output circuitry
used and the transistor they require 12-28v power supply. Layout
is somewhat critical.

Horizontal deflection transistors generally have an FT way too low
to be usefull much higher in frequency than the 160 or 80 meter ham
bands. Sweep tubes are now rare and expensive bottles costing more
than 'common' 6146 types. Surplus 1625 tubes used to be only a few
bucks each, can be found for about $5-10 each at hamfests and fleabay
(Still cheaper than 6146's though). 807's cost a little more.
The best bargin in price vs power might be the 811A, or the 813.

BTW I have a bunch of 813's I'd be willing to sell. Someone make me
a good offer on a lot of 5 of them. (Used, but don't look too bad).

Hi Ken,

It depends on the TV but all this has been 20+ years ago. In those days I found a few transistors that made great shortwave amps. I believe their part numbers pretty much all started with BU. When one type fell out of favor with the TV manufacturers they showed up on markets by the carton. Usually at dump shops or discounters.

The other types that worked even better were the video transistors that drove the CRT. You had to secure a cheap source, no scavenging out of TVs because each set only had three. But they were low power so that required a soldering marathon and it only made sense when you could buy them a dime a dozen. We used to do some crazy things such as running them oil cooled because these weren't easy to mount on a heat sink.

Except for the CRT drivers the data sheets mostly didn't spec FT, just switching times. But that used to be the same with small signal types such as the BSS123 that I have used heavily in front ends.

Seems to me that if you're not sure how you ended up with it, then it's not suitable for anything, because you don't know when it'll change to something else nor how to make it happen reliably.

One way to end up with a waveform like that is to pass random noise into a comparator. Another is to use a shift register to create a pseudorandom sequence generator, and then look at one bit of it.

You are not following me here, I am talking about accuracy here.
Stick your ohm meter on your Marconi generators RF output
connector and click through the ranges. You will see a nearly
constant resistance reading. A small variation in resistance
reading is acceptable. No variation is prefection. A large variation
in resistance reading, such as short circuit or open circuit in any
attenuator switch position means it is stuffed. Just for interest
tell us what you measure.

Someone may have transmitted into the generator or connected
it to a large DC voltage (wihout a DC blocking capacitor) when
testing a radio. That sort of thing happens all the time.

In one place I worked at there was an HP 8640B sig gen.
It had reverse RF protection and DC protection. You could
hear a distinctive loud click when the protection circuit
operated. The guy using the HP8640B would then look
sheepish and embarrassed because everyone in the work
shop, boss and all, knew he had shoved RF or DC up the
brand new (at that time) signal generator. All the other
signal generators were being silently zapped in that Racal
two-way radio factory. The man fixing the many signal
generators in that factory got the shits after a while. He
insisted that an external pad be used. Meaning, all he
had to do was open up a tiny external box and replace
the burnt out resistors and not open up the sig gen.

The point I am making is all attenuators are suspect
because they are so easily damaged, I have done
it my self. Pushed some stuff on the bench to one
side and the mic button on a transciever connected
to the sig gen got pressed.

We are talking RF here!
If you examine your marconi attenuator you will see it is probably
a beautifully made cast aluminium assembly with a switch built
into it. It will be a top quality switch with beautifull silver
contacts. Each little resistor will have its own little compartment
in that beautifully machined solid block of aluminium. SHIELDING!
We are talking about shielding! A pot just can't compete
with an attenuator like that shielding wise.

>
>Er, I *do* have a scope. Might that not be better or are you looking
>for something a scope wouldn't show up?

We are talking microvolts here. Your scope, whatever it is,
will have a maximum sensitivity in millivolts. If you see millivolts
of RF by waving your scope probe near your sig gen then
your sig gen is useless. All you will see is a noisy 50 Hz
waveform.
The RF signal should come out of the signal generator
via the attenuator and RF connector and no where else.

Two way radios, work down to one microvolt or less.
General purpose scopes don't.
If a radio can hear the signal generator and it is not
even connected to it on the desired channel frequency
or any of the IF frequencies. It means an RF signal is
leaking from the case of the generator. The attenuator,
should be the controller of all RF leaving the sig gen.
A leaky signal generator as a service instument for
measuring receiver sensitivity is useless.

So before spending any money on the AVO sig gen,
check to see if it leaks RF. If it leaks forget it.

I only mentioned the Marconi 144H on ebay because it
is easy to repair by hobbyists, performs well, is cheap,
has industry standard 50 ohms output Z. circuit is available,
the unit is for sale just up the M1 high speed motorway
near you. I thought I would be helping a beginner who is
struggling with filters and may need a second good sig gen.
I'll get out your hair now. :-)

I am having great trouble locating the operations and service manual for the Wavetek 3000-200 Signal Generator with Option 200 Deviation Meter. If you have one I would like to buy it or a copy, digital or photocopy.

Reply to jmcmann{+A+T+}pacbell.net. You can figure out that you need to remove the stuff between and including the { } and insert the @ sign. Sorry for the trouble but you know how the spam is these days...

Thanks,

Jim McMann KF6WOR
San Jose, CA.

Randumb duty cycle modulation would only alter the lower harmonic
spectrum; the rise anf fall times are the major source of frequency
multiples.

> P.

Think about it this way: say it has at least one 3f half cycle per 30
cycles. Therefore if you feed it to a high Q filter that rings at 3f,
it will duly give you 3f.

But only if the 3f is present in the original wave. To ring at 3f off
one half cycle per 30 cycles it needs to be reasonably high q, and a
high q filter is not going to work off 2.7f, so a fixed pattern is
going to be better than a random pattern that might not contain the
right f at times.

I wouldnt be surprised if someone critiques this 'visual' analysis
though, I wait and see.

Regards, NT

Paul:

There is an interesting two part article in QST May & June 1997 describing 300 W and 500 W output Class E (more efficient, non-linear) amplifiers using a single IRFP440 (300 W) or IRFP450(500 W) at 7 MHz. Since you are in the UK, there is a brief mention in Radcom (Technical Topics) August 1997.

Ordinary garden-variety power FETs can also be used for HF linear amplification using appropriate bias settings - though exactly how linear they can be in practice I don't know.

==========
MOSFETS can be used for RF applications provided the input and output
capacitance is sufficiently low.
I recently bought a power module from a surplus store with 48 pcs HUF76143P3
Hi-speed MOSFET in a TO220 package ,all for Euro 4.00 (just under US$5.-)
The relevant spec sheet says Input cap.= 3900pf , Output cap.=1600pF
,useful up to 1 MHz.

Most MOSFET studded RF power amps circuits I have come across are equipped
with IRFxxx range of devices.

ok,

Can you tell us how long will the wire be that you are winding on your coil ?

I agree that the smaller ga copper or silver could be the better way to go.

What is total weight of the coil using the al wire compared to cu or ag ?

If the drain load is resonated and you want some control over the resonant
frequency (i.e. you have external to the mosfet tuning Cs) I don't see much
discontinuities in inductors current. Of course when all the stuff is well
"wired" and that's an entirely different matter, isn't it Paul ? ;-)

John, can you suggest some refs that nicely snap ?

Thanks,
Fred.

Okay, well the vast majority of the positions are bang on 50 ohms.
About 7 are 51 ohms and after that point, the very end of the range
goes one ohm at a time up to 56 ohms as the worst instance. I guess
that's acceptable?

>Still 0 bids.

How the hell do you find this stuff?
Don't tell me, that was a rhetorical question. :-)
The thing is, John, I rather like the *look* of my AVO. What's
stopping me from just hooking up an external, switched attenuator?
And you say the use of pots is cheapo, but this is an ex-military
piece of kit withe MOD record stamped on the front. The military don't
buy junk - well, apart from Nimrod, that is.

>We are talking RF here!

Oh yeah. I'd forgotten about that. Plus the AVO goes up to 250Mhz,
too, so it's even more important. Not bad for its day, though!

>via the attenuator and RF connector and no where else.

It does. There's no leakage whatsoever from the case. Nonetheless, the attenuator appears to be shot to bits. I either get full output or nowt but jitter. But I can't bear to junk it so I'm going to (in due time) try to replace the pots. You can't really blame me, can you? It'd be a sin to chuck one of these onto the trash heap. It would also make a very nice looking ornament for the mantlepiece; looks a lot nicer in real life than that photo I took.

>Two way radios, work down to one microvolt or less.

It's not leaking one iota.

>near you.

Hey, "near you" in Australian terms, sure. But this is a very overcrowded little island indeed! The M1 ain't no "high speed motorway" except maybe at 3am. And to get on it in the first place I'd have to circumnavigate the London orbital M25 "The Road to Hell" in the Chris Rea record (and if you want to know why, just listen to the intro to part 1 of the record). The only alternative is attempting to drive straight across London, which would be even worse still.
Yeah, it's a great deal, but the guy won't deliver or post, so he might as well be on the dark side of the moon as in Bedfordshire, I'm

afraid, notwithstanding it's less than 150 miles away. :-(

>I thought I would be helping a beginner who is
>struggling with filters and may need a second good sig gen.
>I'll get out your hair now. :-)

I was a "beginner" 35 years ago. Obviously I'm not making much
progress. Thanks for the advice, anyway, it's always valued.

I think that most mosfet substrate diodes are now designed to have
soft recovery, so that they won't snap and make a horrible dv/dt. I
blew up a lot of early Motorola mosfets in an h-bridge motor driver...
had to switch to darlingtons, and only figured it out later.

Anything with a p-i-n structure has a chance of being a snap diode. I
think it needs a hyperbolic doping profile or something to work well.
1N4005-7 types work, but usually only after a brief forward bias, not
DC. Somebody told me that many varicaps snap, but I haven't verified
that. Specifically-designed PIN diodes (the kind used in RF switches
and attenuators) don't snap, as they are doped to have very long
recovery times.

We tested over 60 different TO-220 power diodes to find the best
high-voltage drift step-recovery part. Then we found something else,
much better and more repeatable, but that's still a secret.

John

In case anyone cares I have an update on this. I was able to get a crystal controlled RF module for the transmitter and that took care of the problem. It's definitely the synth RF module that's experiencing the interference.

I'm still interested in findind a way to deal with this aside from just not using the synth module at that site. Now that I've more or less isolated the problem, is there anything I can try? I did make an attempt at sheilding just the RF module with no luck, but are there other options?

Thanks.

Have you tried Wavetek? They still have manuals for old equipment, even
for things that were made by companies they merged with.

As long as it's at the transmitter, you could try a bandpass filter. Chances are the interference is coming from outside the RC band. There are programs available for free that will give you the numbers you need. I use one called AADE Filter Design from AADE.com . Ask if you need info on making the inductors etc.

I'm sorry, but I've not been keeping track of what kind of problem you're trying to solve. It sure sounds like you're trying to reinvent some sort of wheel here, though.

If you are trying to start with a noise source in order to generate a signal at a specific, adjustable frequency, then surely you must consider that the way to do that is to filter the noise source; and that the task of making a good tuneable filter is no different than the task of making a good tuneable oscillator. And starting with broadband noise is not generally a good approach to getting something quiet.

Modern commercial radio transmitters (including FM band, 88-108MHz) by,
e.g., Harris use MOSFETs. So clearly it is possible to get up to 25kW. I
believe they also use them in 100kW AM band transmitters. A bit of
meandering on Harris' web page will tell you more.

I rather doubt that there are any tube-type 50 kW AM broadcast band transmitters sold these days. The 50 kW solid state Harris unit seems to be extremely widely used. Such transmitters use lots of hot-swappable modules - and can operate quite well with a few modules removed. At least some of these high-power AM rigs are essentially huge D-to-A converters. Look in the IEEE Transactions on Broadcasting for some ideas.

The 88-108 MHz units are conventional amplifiers, made of a number of modules and combiners.

The trick in the near future is adding IBOC digital to these rigs without non-linearities and unacceptable mixing products. Although "digital", the RF is of course analog in nature. I gather that solid state rigs accommodating IBOC were at the NAB show a couple of weeks ago.

When WTOP was running IBOC tests on 1500 kHz I don't know whether they were using their main solid state 50 kW Harris rig or the tube Continental 50 kW backup.

Use the escalator? =oD

Maybe separate your tools into two groups and get two Samsonites. I have a ton of tools at home but when I go to work on a friend's car, I can leave most all my tools at home and bring application specific tools that are light enough to carry in a backpack. I can't even imagine how long it'd take me to get all my tools from my rollaway into my car, much less just trying to lift my top chest without removing any tools from it first. =o)

Good luck,

-Bruce

> tunning a negative resistance?

A coaxial resonator will resonate on (or near) odd harmonics of the
lowest resonance, but you'll probably have trouble getting an LC tank
to have significant response at harmonics. Then the tuning will be
problematic, I think: you need to cover 3:1 for the lowest resonance,
and only 5:3 for the second, 7:5 for the third, etc., but capacitive
tuning would need a capacitance for the lowest resonance which is
awkward for the higher ones. Maybe you could only use the resonator,
say, at and above the 7th harmonic of the lowest resonance, and forget
about the 1st, 3rd and 5th.
>
> Perhaps with the use of a "register key", such as is on flutes and
> clarinets? I suppose that functions as a high-pass filter on the line,

Just as an overtone crystal oscillator selects the overtone, you
should be able to do similarly with a coaxial resonator oscillator.
There's likely a practical limit. (The coupling will change with
which resonance is selected, no?)
>
> I'm interested in a multi-decade VCO, tuned with one control voltage and
> just a few switches.

You can switch both the C and the L of an LC tank and cover a wide
range...but it's often easier to just build separate oscillators and
switch among them.
>
> No, I don't want to heterodyne or synthesize, because I'm interested in

>
> Any applicable app notes or articles? Dream on?

I predict there will be a whole lot to learn on your way to your
goal...but remember the old regen radios that used plug-in coils for
different bands? Some of them could cover quite a range. You may be
able to accomplish something similar with diode switching.

Cheers,
Tom

Pukes? I guess you're applying that term 'affectionately' since we're the ones you're asking for help. I can't add much to the answers already given, unless there is something like a lift or elevator on board. Some of those cases are modular, with a series of stacking boxes. Perhaps, like others have suggested, you could divide your stash into several piles, and only move the ones you actually expect to need at a time.

What do you need that many tools for anyway? Kind of like the golfer who takes a bag full of golf clubs to play a par 3 course. Take only what you need in a smaller case, and leave the rest in your workshop. Seriously, I have worked in industrial plants where I had a over a hundred pounds of tools in the shop, but usually carried a collection of tools that would allow me to do 90 percent of all jobs I had to do. A lot of the jobs I would just grab a pair of longnose pliers, a couple of screwdrivers, and my meter.

I should have said helping a fellow beginner and hobbyist. I am
in the same boat as you, continually struggling. So I know what
it is like being in the dark and feeling my way. :-)

Getting back to your external attenuator idea.
I often buy dud damaged boat anchor sig gens, for a few dollars
at ham meetings/trash and treasure buy and sells, in the hope of
finding a nice attenuator. I have humped a few monsters home
only to find rubbish inside. I have been lucky a couple of times.
There are plenty of ready made attenuator units for sale
usually for big dollars from a hobbyists point of view.

Have a look at this one.

Their AM transmitter combines the outputs of 60 some modules to get the
instantanous PEP they need. All modules are fed the same square wave signal,
and modules run class E (I think). They don't say what the sampling rate is,
but I would guess ~20 KHz. There is a WLW related web site that has more
info than the Harris site. If I run across it again, I will post it.

Directly parallelling the semiconductors have several drawbacks. First
of all, the capacitances are in parallel thus limiting the frequency
response. Also load sharing between the semiconductors can be hard to
achieve.

>Modern commercial radio transmitters (including FM band, 88-108MHz) by,
>e.g., Harris use MOSFETs. So clearly it is possible to get up to 25kW. I
>believe they also use them in 100kW AM band transmitters. A bit of
>meandering on Harris' web page will tell you more.

They are complete amplifier modules with well specified output
impedances that are combined. If e.g. Wilkinson dividers/combiners are
used, these have a limited bandwidth, but this is usually not a big
issue in broadcasting, in which the frequency remains the same and if
changes are needed, the relative frequency range is limited.

However, Wilkinson dividers and combiners would not be suitable for
1.8-50 MHz amateur linear amplifier due to the huge relative frequency
range.

3663. VCO noise - update

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-07 06:55:14 UTC
From: Alex Collins <me@privacy.net>
Message-ID: <2g0q48F34vb6U1@uni-berlin.de>
Source record: 26100

Thanks to everyone who replied. I've now discovered the reason for the disastrous noise on the Mini-Circuits VCO: Obviously I was using *extremely* good RF PCB design techniques/layout, but these devices need even better than the very best. They are abnormally sensitive - not so much to noise on Vtune (20V tuning devices are less sensitive than the 5V wideband types) - but to earthing - much more than normal - and much more than Mini-Circuits own suggested PCB layout for the device suggests. And despite the fact that the tiny metal can is mostly directly bonded earth pins. It's not feasible how bad the results can be, even on a very good RF board! Apparently, the quoted -75dBc phase noise figure is almost unattainable, except using Mini-Circuits own metal block test jig.

I've spent a week questioning myself and my Analyzer, so I hope this might help others to get acceptable results using this device. Use vias everywhere, solder the can all round, really go over-the-top on everything, in addition to all the normal RF grounding/decoupling practices, and then you might just get barely acceptable results.

Al.

Amazing! I don't know how you find this stuff, John. It seems like an
excellent buy, but there's just one small problem: the Zout of my AVO
appears to be 75 ohms. I know that's 'getaroundable' but it takes the
shine off it. I'll try changing the pots first, then I'll borrow a VNA
and see what gives.

Swiss Army Knife ?

3670. Re: VCO noise - update

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-07 13:32:36 UTC
From: TOM <noname@noprovider.nodomain>
Message-ID: <UdMmc.94121$G_.41677@nwrddc02.gnilink.net>
Source record: 26104

The problem is the tuning voltage, and how sensitive it is. This applies to all wide-range VCO's.
I can't find the original message, but here's an example...

Assume VCO tunes 1GHz to 2 GHZ with 20 volts of tuning voltage. While the tuning voltage
is not linear, simply to linear assumption. Then the sensitivity of the tuning line is 1 GHz / 20 volts,
this is the same as 1 KHz / 20 microvolts. It's really hard to get noise levels that low! Practically,
the entire VCO as well as the circuit that drives the tuning line and all the componenets therein
have to be inside a well shielded enclosure. Further, extraordinary care has to be taken in grounding.
This means figuring out all the noise sources, ground return paths, etc. You cannot just hook everything
to a groundplane, that's nowhere near good enough. It's necessary to group 'vias' to the ground plane
based on which return currents they share, and then wire each ground connection or group of
connections to the exact specific via needed. One cm of groundplane can have millivolts of potential
difference across it.

I don't think measuring -75 dBc/Hz at 1 kHz requires superhuman effort.
It does require an understanding of the measurement process and the
nature of the device being characterized, though.

Presumably that depends on how "suitably noisy" your diode is, and how fast
your Schmitt trigger is.

Here's a project for you: how can you describe the behavior of a
(real-world) Schmitt trigger in the frequency domain, that is, in terms of
how it affects a signal's frequency spectrum?

COME-ON, guys! He came to rec.AVIATION.HOMEBUILT asking this question.
What he wants to know is:

A) whether to use a laminar or turbulent airfoil, and what's the proper
wing loading for a toolbox?
B) would a certified or auto-conversion engine be more appropriate?
C) composite, aluminum, or tube and rag?
E) electric or manual trim?
F) circuit breakers or fuses?

Now. Could somebody help the guy out, please!

That's very useful, thanks! I downloaded the program and think I
understand it well enough to plug in the numbers. I do have one big
question though. How do I measure the impedance? I've got a basic
VOM but that's it as far as test equipment, and my knowledge of things
electronic is pretty basic.

Could be the analyzer is noisey...

Try measuring additive phase noise with two VCOs at the same time using a phase shifter to calculate the detector constant. subtract 3dB from your measurement.

Just got the lot of 400+ crystals I won on ebay.
Turns out they are NOT HC49/u rocks, but HC6/U!
Isn't it ture that the larger crystals are better
for use in filters than the smaller one's (higher
Q, less loss, etc?)

Looks like some fun ahead experimenting with
this and maybe a homebrew spectrum analyzer in the
works to scan around 8.3866mhz (in my test oscillator
I'm getting 8.389855mhz, better let the oscillator and
the frequency counter warm up for a while).

Time to smash some surplus 9pin tube sockets up for
crystal socket pins ....

While Q comes with cubic feet (of space around inductors and capacitors) it isn't the only factor when it comes to crystals. There, it's mostly surface finish, cut and the amount of plateback used to place them on frequency. You can have Q of several hundred K in the small HC-49, and less than 50K in the larger holders. (Crystal itself may be larger or smaller, doesn't HAVE to go with the can).

Have to measure a representative sample to determine the average, I haven't seen a crystal made in recent years with really high Q. Quality control folks have learned how to take all the quality out and make them cheaper.

After WW2, some manufacturers bought up all the FT-243 crystals they could find. Chopped the wafers into tiny pieces and made really good crystals for many years.

Oh, yeah, I didn't consider that your antenna is not 50-ohms. How long is the antenna, and what frequency band are you using? 72 MHz? When it comes to calculating what your antenna looks like impedance-wise, there are others here more knowledgeable than me and I hope they jump in! I wonder how well shielded the transmitter is, also. If not well shielded the interference could just get in directly and the BP filter wouldn't help. There are devices that allow you to measure an antenna's impedance, but they cost about what your transmitter cost.

Maybe they're designed for a circuit with parallel C, not series type..

You're probably intending to make a sweep generator and view the bandpass on
a scope, right? This site has a suitable sweep generator
http://www.intio.or.jp/jf10zl/

> Time to smash some surplus 9pin tube sockets up for
> crystal socket pins ....

But you're going to solder the xtals directly to boards for the actual
filters, right? You could make a board pretty easily, all the xtals having
the same pin separation. Lotta drilling.

Inspired by you I bought a bunch of HC-49s on eBay. They will plug into a
DIP socket, which is what I'm using in my measurement jig. Buffered
oscillator running off 9 V, no pulling when I hook up the counter.

I have no idea. But remember other factors come into play.
Traditionally, only a handful of crystals were comodity items.
You could buy surplus, or you could get crystals for a handful
of frequencies that were premade, but generally you had to have them
specifically made for the application. I imagine (but don't know)
that such crystals tended to be better quality than a commodity crystal
from today. If nothing else, you were paying more for them.

And HC-6 holders tend to suggest something older, and hence maybe
dating from a day when more effort was put into making the crystals.
But that impression is not about the size of the holder, but about
the era of the crystal.

Of course, I've come across mass produced HC6 crystals so even then
it may be no indicator at all.

Message-ID: <fd1add4f.0405072006.406174e6@posting.google.com>
Source record: 26125

#1.) I recently built a basic Hartley VCO and made measurments on it
with a scope.

#2.) I thought that I would make a model of it with Micro-Cap and see
how well the simulation matched the real thing.

#3.) I used 2 inductors to model the torroid(probably a mistake).
When I simulated the VCO it worked. However voltage measurments of
the top part of the inductor and the lower part(tap) were in phase.
This did not match my scope measurements of the real thing.

#4.) Is there a model available in Micro-Cap for a toroid?

#5.) I also have access to Micro-Sim Pspice. Is this a better
package? Is there a model for this package?

Thanks!

Greg

So long as you are not driving the toroid to the point of
nonlinearity, a model with two standard inductors in series should
work fine for a tapped toroid winding. If the mu of the core material
is high, the coefficient of coupling between the coils will be quite
high; it will be somewhat less if the core mu is low (like one of the
high-frequency powdered iron mixes). The one time when I got really
serious about using a toroid-core transformer model in Spice, a linear
one worked just fine, but I did take the time to characterize the
physical transformer's parasitic capacitance, leakage inductance and
effective resistance. In fact, I was amazed at how accurately the
Spice output matched the overall circuit performance in that case.
(3.5MHz switching power supply, using a LAN transformer -- the ringing
and damping of that ringing of the parasitics up near 100MHz matched
what I measured in the circuit almost exactly.)

Cheers,
Tom

Yes I built a similar oscillator, a bit cruder though
I clipped my scope probe to the output and connected the
probe to the counter. I noticed that the frequency drifts somewhat
when the crystal is first plugged into the test oscillator. I
guess I need to let the frequency counter warm up for about a
half hour before taking any measurements, the oscillator may
also need a warmup period, and perhaps even the crystal.

If you handle the crystal while inserting it into the socket
the heat from your hands probably affects the crystal, though
I noticed that if I continue to hold the crystal with
two fingers things stablize more quickly (is my hand acting
as a crystal oven?) Total drift is under 250hz.

Highly recommended reading;

"High-Performance crystal filter design" by Bill Carver, Communications Quarterly, Winter 1993.

Addresses the same problem and lots more, and unless you plan on permanently attaching your fingers to your filter, you'd better pay attention.

I was just looking through the Digikey catalog for a 200Vdc, 220uf, radial lead capacitor. No problem I thought, until I got looking.. Can anyone tell me, or point me to a web site, that explains all the different series of capacitors?
They vary in price from around $2 up to $8.

I used an untuned buffer. Listening on a receiver when I connect the
counter, I hear no pulling. Sounds like your counter needs an oven! Based on
what you're saying about hand temperature moving the frequency, I am
expecting to see an article on passband tuning using a lightbulb driven by a
variable regulator, mounted next to the filter and BFO xtal. "Passband
Tuning Via Thermally Induced Piezoelectric Deformation."

But is it temperature, or finger capacitance.

Look at any circuit board, and the crystals will have the case grounded.
Look in any old two-way radio, and there is a grounding clip at the crystal
socket. Now, maybe this is for temperature stability (connected a larger
mass to the case stabilizes it) but I think it's due to the case coming
into play.

>And the reserve price hasn't been met! Silly hams.

Whatever floats your boat. I have seen many give thousands for a restored car that cost very little new. Different people have different interests, doesn't necessarily mean they are silly.
I bought an AC-1 in 1962 for about $19. I built it and when I finally got it working, I had the tubes in the wrong sockets, I had the most fun I have had in 40 years of ham radio.
Would I give $300 for a restored AC-1, no, nor would I give $25,000 for a restored '66 Mustang. There are many that would. Are coin, stamp, or fill in the blank collectors silly?

The DigiKey catalog itself has info about the salient features of the
various series. Perhaps you want to know specifically what to look
for, what matters. Key variables are the ability to handle ripple
current and maximum operating temperature. Also, some are rated for
high-frequency use...best to not use a low-frequency one in a critical
point in a switching power supply, where it would have a high ripple
current at the switching frequency.

You can also go to the manufacturers' web sites and find info on the
various series, and occasionally even find application notes.

Cheers,
Tom

Get the bosun to carry your tools or help you carry your tools.
Webbing strop and ships winch.
Check out each job before starting and take less tools in a smaller
case.
Keep your own tools at home if the shipping company supplies tools and
use your own tools for homers when off tour.
See about your addiction. :-)

I managed a whole week once with a pinching driver!
I am a professed tool junkie as well but my van has no organisation aids
in it so there are tools and materials stuffed in the back of it so much
I can't find the tools I need.

Point taken - and if you were going into the woods to catch a deer,
(or a bunny rabbit) you would at least have a skinning knife with you
and then take the skin back home to tan - the same with repairs, I
have a swiss army knife on my belt and I can do a huge number of
repairs with that. And if you are on a "boat" then you wont have to
drive 15 miles to get the right tool, would you. So, if you want to
lug a 20Kg toolbox up and down "stairs" then feel free to do so - dont
expect to do it any other way, because there isnt one.

Oh, and BTW - on a "boat" you are unlikely to find that a new piece of
equipment needing an unusual tool has miraculously(sp) appeared
overnight - wish I had it that easy!.....

There are perhaps a dozen or so available. My favorite is the DXLabs
suite of applications, which is freeware and available at

http://www.qsl.net/dxlab/

The individual programs can be run alone, but the real power of the
suite comes from the way they interconnect with each other. This may be
more power than you need, but it will do anything you are likely to ever
require. It's completely free and contains no advertising. I wouldn't
be without it.

3712. FS: Homebrew Radio Goodies

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-09 20:06:52 UTC
From: Marv_E_Ads@juno.com
Message-ID: <d6222070.0405091206.6c33b319@posting.google.com>
Source record: 26149

*** Homebrew Radio things ***

Many hams build things with a large investment in time & parts that are
worth far less... later. Here are some items from the estate stuff I've
been selling that fit that description -- priced accordingly.

Unless noted, most of the items below are built on PCB material and most
of the enclosures are made by soldering pieces of PCB material into a box
-- not all sides may be present! Batteries not included! A few of
these devices come with schematics, mostly not. The wiring is all open
enough that you can generally see what is going on.

Battery drainer -- LM317K (TO-3) plus a pot wired as a current sink to
drain batteries -- 4" x 3" x 1.5" -- $1

PL Tone generator -- Wein Bridge Oscillator powered by two 9 volt
batteries (not included). - $2

Touch Tone Encoder -- Western Electric Touch Tone Dial mounted in a
4"x4"x2" metal enclosure with power switch. Has a 4 pin DIN connector
plus matching cable terminated in a 1/8" mini plug. $3

Some kind of test oscillator with a NE556, two pots with anodized gold
(colored) knobs, pwr. sw.. LED,. & Banana jack outputs -- $3

HF Harmonic Filter built in a 5" x 2.25" x 2.25" LMB Aluminum box. UHF
connectors. Probably good for 100W. $5

Digital Clock insides -- National MA-1001A demo board with MM5385N IC
plus 5 digit LED readout connected to another small PCB with a
3.579MHz clock circuit & MM5369N 60 Hz diveder. $5

60dB Sampling Tap -- HN female connectors for the main line and a BNC for
the tap. 1KW in the line puts 1mW to the tap. -- $10

435 MHz power splitter with (3) N connectors. This is made out of brass
sheet stock and is about 15" long by 1" square. $10

Varactor multiplier (unfinished) -- looks like it's designed for 144 to

432. Built in a 3.5" x 2" x 7/8" extruded aluminum case -- top plate missing. Silver plated coils, Johnson 189-6-4 caps. It think it is complete execpt for the input and output leads. $10

Some kind of VHF thing just started. Pomona 4"x2.5"x1.5" cast box with a
couple 160-104 capacitors, BNC connectors, a miniature 50K bourns pot., 6
capacitors mounted to gold plated terminals with a very pretty gold flashed internal shield structure. Nothing is soldered -- this was just
started. $10

Antenna Noise bridge? -- Pot & Cap plus 4 transistor circuit mounted in a
5" x 4" x 2" enclosure. BNC connectors marked ANT & RX. Pwr SW. & Led
Powered by a single 9 volt battery. - $10

Two Meter to 24-28 MHz receiving converter (I think!) -- 5" x 4" x 1.75"
-- $10

All of the above plus shipping, if necessary, naturally.

There are as many answers to this question as there are hams<grin>...
Seriously, there must be dozens if not hundreds of logging programs out
there. The ac6v.com link posted elsewhere in this thread is a good
place to start looking.

I'm not entirely sure I know what you mean by "identify contacts".
Usually that's done by copying the other guy's callsign over the air.
(arguably, you don't have a contact if you didn't copy the other guy's
call over the radio!) Or do you mean to find more information about a
station once you've copied the callsign?

There are databases that will cross-reference callsigns to names &
addresses; www.qrz.com is a popular one, I think they also still sell
their database on CD so you can use it even if you aren't logged onto
the 'Net. There are simpler databases that will cross-reference a
callsign to that station's country. In some logging programs, this
lookup function is part of the program; in others, a separate program is
used. (often, just a web browser)

As for my own station, I have a homemade program running as Perl CGI
scripts on a computer in the den; QSOs are logged in a MySQL database,
and the Windows computer in the hamshack attaches to the webserver in
the den to log(/search) QSOs. Works pretty well, though I don't have
any of the address lookup functions. (guess I should add that someday)

Perhaps the OP could spend more time at the gym? ;-)

I, too, find that my little Gerber Tool solves well over 90% of my
'occasional' tool needs. While there's hardly a tool on it that I would use
for a particular job if I had the 'real' tool at hand; the utility of having
all those tools on my belt--all of the time--is liberating.

I have an old HP 141A spectrum analyzer. Similar to the 141T.
Can someone tell me if I can plug in an 8553B RF unit?

How about an 8555A RF unit? I know it is to be used with the 141T but
will it work in the 141A also?

Thanks for any help.

Try the freezer - lasts MUCH longer. That's where I keep mine. It only takes a few minutes to defrost (good conductor) and keeps for years, even with the occasional defrosting.

Ah... thank you, that's the answer I was hoping for.

(Warnings about avoiding cross-contamination to food also noted.)

Yep, I am a tool junkie as well - but I only carry the bare minimum in
the van, paranoid about them being stolen, and commercial insurance is
just toooo much. Lets face it, he who dies with the most tools/test
equipment wins......(not sure what you win, I just know that you do).

BTW - whats the most obscure specialised tool you own - you know,
something that was acquired in a moment of madness and never got used
- (this specifically exludes power tools, they are in a special
"sacred objects" category)...and where can I get a micro lathe cheap
for turning up capacitor shafts....

I almost forgot mine on my belt at the airport once. Luckily I
remembered in time and was able to run back and stick it in my checked
baggage. I was almost sick at the thought of having to turn it over to
Security.

I would rather leave my wallet at home than my Gerber. It's saved my
bacon more times than I can remember. Best $40 I ever spent.

Mike

3732. Frequency counter

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-11 05:08:23 UTC
From: Mike Burch <mburch46@mchsi.com>
Message-ID: <bdZnc.24361$iF6.2538606@attbi_s02>
Source record: 26168

Hi Fella's,

I would like to add a small frequency counter to the front of my heathkit IG-102 signal generator. Its the old tube model with the gray front. The counter would have to go to just 110 mhz, be small and have an led display but lcd would be an acceptable second.
Do any of you have any recommendations on kits?
Thanks in advance for any input.

Mike Burch K8MB

I'm not surprised they are still available, at the prices you are
asking. Wholesale quantities of LEDs and resistors are available far
cheaper locally here in the UK.

(Or perhaps, when you posted to uk.radio.amateur, you didn't realise
that 'UK' is not a state of the USA.)

I'm sure this is in the handbook, but darned if I can find it.

I'm using a MAR-6 after a DDS and filtered output for a little gain into a passive mixer, the DDS will be used for 1-30 MHz or so, how do I calculate the value of the RF choke at the DC supply side? I hope this question is at least coherent...

It's optional, especially at such low frequencies. I wouldn't bother with
it, just use the resistor mentioned in the data sheet.

I'll assume you mean an electret type microphone? I don't know of anyone who
makes a condensor microphone anymore. Those things take 500 volts of extremely
well filtered DC and the impedance is purely the capacitance of the plates.
Crooners hated them in the old days because if the stage electrician screwed up,
they could get the entire 500 volts on their lips as they 'kissed' the
microphone.

Figure 2.2k to 4.7k for electrets with three wires. On two wire types, set the
impedance with the bias resistor size. You can get more sensitivity by
increasing the drain resistor, but you sacrifice high frequency response and
dynamic range if you go too far with it.

Electret. Someone told me they're also now available with a SMD
transistor amp built-on.
Just a ball-park figure would suffice.

Can't you just up the frequency of the converter a bit? That would reduce the flux density in the transformer, or the filter choke inductance, depending on the type of converter you use. A reduced flux density would allow the use of smaller cross section magnetics and less turns of wire. The net result is a saving in weight and cost. Then you may consider the use of copper wire. The wire losses only go up as the square root of the frequency for solid wire, and the wire resistance is primarily determined by skin effect once you get up past a few KHz in frequency. In fact you will have less total losses using copper Litz wire of a size smaller than using solid aluminum wire.

If your current requirements are low you can "manufacture" your own small gage Litz wire of sorts by twisting together a number of strands of fine solid round magnet wire. The size of the wire strands depends on the frequency of the current the wire must carry. If your requirements are real small some of the Litz wire manufactures may have some left over scrap of a type you can use they would sell you.

have a look at the unicounter by ron stone in qst.
when i first saw it (a 1-digit freq counter) i thought what a useless
idea!!!!!
when i saw a morse person in the radio club enthusing over a morse freq
read-out i went back to the uni-counter
read it again, made one, and then e-mailed ron s to apologise for writing
off his handy-work so unjustly!!!
it is SUPERB!!!

3753. DDS chips

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-12 01:49:44 UTC
From: Ken Scharf <wa2mzeNOTTHIS@bellsouth.net>
Message-ID: <Tjfoc.523$U4.239@bignews6.bellsouth.net>
Source record: 26189

For those trying to solder those TSSOP and TQFP AD chips into a circuit I found this site on the net

http://aprilog.com/perl/main.pl

They sell adaptors to solder the chip onto to plug into standard dip sockets.

There are other types of breadboard circuit boards for these chips as well. Search on google for "TSSOP breadboard" or "TQFP breadboard".

Now that I see it might be possible I'm going to try and make use of those 9954 and 9851 chips I got as samples. The 9932 looks interresting too, with it's low power. I also want to get a sample of the 9834, now THAT's a low power chip, perfect for QRP.

Anybody have any 'war stories' about using these DDS chips in a rig as a vfo?

3754. Re: DDS chips

I think the problem with these is going to be placing the bypass caps close
enough to the chip, and also getting good low-impedance RF ground paths.
For just a little more money, you can buy an entire DDS board with all parts
from NJQRP.

Let us know how you make out.

Joe

The Aprilog adaptors do work. I've used them on both AD9852/AD9854 chips and ATmega128 chips. Drawbacks are: 1) they aren't exactly free; and 2) Aprilog can be a little quirky to deal with at times, although they've always come through for me in the end. (I think it's a one- or two-man shop that sometimes gets overwhelmed with business.) They will sometimes cut you a good deal on slightly-nonstandard stock.

They are certainly preferable to hand-soldering. I'd say give 'em a try with the 9900-series DDS parts and report back to let us know your results.

Easiest way to answer that would be to go look at some manufacturer specs.

I'll ignore the distinction between electret and condensor and going with common usage, and assume, without justification, that you are talking about the output impedance at the XLR connector of a balanced mic. In other words: you want to know what the output impedance of, say, a Shure SM87 or an Audio-Technica AT4033 is. Answer, based on a quick nonsystematic sample: about 100 ohms on average.

But I'm not sure why you care. Like the rest of pro audio, they're not intended to be loaded by an equal impedance. Generally they want to see around 1k.

As others have noted, this has nothing whatsoever to do with the impedance of the actual mic element, which is basically a capacitor with a fixed charge on it.

Thanks, but I appreciate that, Walter. This is simply for simulation
purposes. I just need to have a value to bung in the signal source box
or the gain of this amp stage will not be meaningfully calculable.

There are hand trucks with electric motors on them that drive grips
that allow it to climb stairs. You just get the truck in position,
push the button and the electric motor (geared way down) takes the
load up or down the stairs.

Would that work for you?

Well, don't be too excited just yet. Even though the chips themselves might be on a diet, they need a high frequency oscillator to get a decent waveform out. Those little oscillator cans start to draw amazing amounts of current when the frequency creeps up. Heck, the ocsillator on my 9850 DDS draws more current by itself than an entire K1.

FAR circuits has a DDS board that is a little more complete than the NJQRP dauhtercard, if that's what you are looking for, but the quality of that board has been pretty bad. I know they are trying to improve it, but I can't say I've been impressed with the results. On the other hand, they do have prototyping boards that are quite nice. I picked up a few at a hamfest this past fall that are pretty decent for the TSSOP DDS parts. And they are a LOT cheaper than the individual adapters. However, their online catalog doesn't have the selection they had at the hamfest, so maybe a call to them would be in order.

The NJQRP daughtercard really does reduce the pain of all this, but both the daughtercard and the FAR circuits DDS card are for the 9850, which is getting a little stale. Sounds like you want to play with some newer stuff.

Also take a peek at some of the TI stuff. They have synthesizers and "transmitter" chips that are very reasonably priced. Although they are intended for very high frequencies, Steve Weber has made them work down into more reasonable frequencies, and prescalers are only a couple of bucks.

Hi:

I am interested in making a simple circuit with SMT components since the IC used comes only in SMT form. Can anyone suggest a kit that can make PCB which is good for SMT component?

Thanks

Do you have any reference to Weber's project? I would love to have a
look at that circuit!

BTW, do you mean SteveN Weber, KD1JV?

Thanks,
Paolo IK1ZYW

If you are making a small number of prototype boards, go to the digikey site and look for "surfboards". They come in various configurations and by using something like wirewrap wire for jumpers between pads a lot of different circuits can be made up quickly. I wouldn't recommend this arrangement for upper rf but anything below 10mhz would probably work ok.

I use the standard UV exposure technique with artwork printed on a laser
printer for through-hole and SMT parts without any problems. You should find
this Yahoo group very useful:

http://groups.yahoo.com/group/Homebrew_PCBs/

Yes the three terminal references should work just fine for you. I have tried some of them and they are great, right on the button.

Hook up two of them and measure the difference with a sensitive voltmeter. They are very close.

You should also look at Lyle Johnson's (KK7P) web page:
http://www.fidalgo.net/~wa7gxd/

Lyle uses the Analog ADSP-2185N DSP chip on a small PC board.
This has successfully been used as an audio DSP with the Elecraft K2 and
the Software Defined Radio DSP-10 by Bob Larkin, W7PUA.

Lyle has an interface board and a number of programs appear in the ARRL book
" Experimental Methods in RF Design", Chapters 10 and 11.
He had updates on the use of the KDSP10 and DSPx in conjunction with this
book.
http://www.fidalgo.net/~wa7gxd/kdsp10.html

Good luck !

0.01% of 12V is 1.2mV, most 3 terminal references have noise which is much greater than this. Something like a Linear Tech LT1963A will get you into the tens of uV -- but all the associated components have to be tightly wound.

If you go into the Linear TEchnology webiste (www.linear.com) and look at the application notes there is an article by Jim Williams which describes a 20 bit DAC -- too complicated to get into here -- what you can do with one of these DAC's would take a Fluke 3330B calibrator two decades ago. www.linear.com/pub/document.html?pub_type=app&document=92

If you are going to calibrate DVM's you'll find some real bargains on EBay under the business equipment/test equipment/calibrator section. It helps if you have a university with a well equipped lab -- you can compare purchases with standardized equipment.

If you're only planning to do one board, you might consider saving the hassle of trying to do it yourself and getting it wrong several times before having success, and using a place like www.expresspcb.com. They provide layout software, even.

I can tell you that the boards that DigiKey sells, and that Circuit Specialists sell, both can be made to work well with SMT parts. I have no trouble with 10 mil traces and spaces, and can do 5 mil if I'm careful, printing the pattern on transparency material with an ink jet printer (in "high quality" mode). I suppose the complete kits they sell would be enough to do the job. You'll need a way to get the layout into a clean transparency.

There have been a LOT of articles on the r.r.a.h. and sci.electronics.design newsgroups about making your own boards over the years. Do a search of the archives (e.g. with Google). There are also a few good web sites. www.thinktink.com is one I like ("PCB Process" on the left side of the home page...); just use what you need and don't go overboard.

Cheers,
Tom

3779. Dolby Digital decoder

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-12 22:30:11 UTC
From: Joel <Joel@cyberbest.com>
Message-ID: <_zxoc.36$al.16@fe25.usenetserver.com>
Source record: 26065

We have a old surround sound 5.1 amp/speaker combination. It does not support Dolby Digital. Every junk DVD player these days has Dolby Digital out. So I need to build a Dolby Digital decoder in to 5.1 out. I can buy a complete receiver that includes the decode and amp. But I don't want that. The PC gang have just the decoders I would need. As the DVD players on the PC's and this card decode the Dolby Digital and have 5.1 out.

It seems to me there must be a schematic or kit to build a hardware Dolby Digital to 5.1 decoder.

Any have any experience like that?

Joe AG4QC

I haven't found a link where you can buy the NJQRP daughtercard, he
seems to have the artwork for downloading but that won't do me much
good. The 9851 seems to be pin compatible with the 9850 and will go
higher in frequency using a lower frequency (lower powered) oscillator.
The 9954 family is much smaller in size than the 9850 family (closer
pin spacing) so dead bug on these would be about impossible, the
circuit board is a must. I found some other bread board adaptors but

the problem is that there can't be any traces UNDER the 9954 because there is a ground pad there. I can carefully cut away the unused portions of one of these (http://www.devrs.com/store/) which is a universal breadboard, drill a hole through the middle and solder a wire to the ground pad. BTW I thought I'd have a problem interfacing to the 9954 because it runs on 1.8v (how to hook it to a 5v 8051?), but the io part of the chip is powered by it's own pin that can run at 3.3v and then it will tolerate 5.5v max on the digital inputs. Problem solved!

BTW many here seem to like PICs, but I'm just more familiar with the 8051 series. IF you don't need external ram or io on the 8031 and and use an external EPROM you still have 16 io lines available, it's then a three chip solution (8031, 74x573, 27x512). There are simulators C compilers and assemblers for the 8051 that run on Linux (don't know about the pics). I DO wish that people that post articles using these micros on the web or in qst would make the SOURCE CODE available!!! Not doing so is like NOT making the SCHEMATIC available for a homebrew article!!!

This coming Sunday....

+++ Now even more Buyers Parking !!!
Thanks to TKT we have use of their new parking lot
across Albany St from the SWAPFEST !!!

!! ** More Buyers PARKING is available ** for details see
http://web.mit.edu/w1gsl/Public/flyer

*** !!!! In our Traditional GARAGE and the adjacent lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday May 16th 2004
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776

********** $1 buyers discount with hard copy of this notice ************

<<<<<<<<<<<<<<<<<<<<<<< cut here >>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>

Mail the coupon below by the 5th of the month to be a Prepaid Vendor.

FLEA at MIT 2004 Rates

SELLERS

This year each vendor must have a Cambridge Vendor License.
We will do all the paperwork to get the one day Cambridge licenses.
To keep the spaces affordable we are discounting your first space.
To use your spaces the named vendor MUST be present.
Rates include one admission per space.

Season Pass $99 First space includes $10 Cambridge Vendor License
$70 Additional spaces
Good for all seven meets this year.
Must be received by April 18th.

Advance $17 First space - includes $10 Cambridge Vendor License
$12 Additional Spaces
Must be received by the 5th of the month.

Gate Admission $20 First Space - includes $10 Cambridge Vendor License
$15 Additional Spaces
Admission is after the prepaid vendors

Early Bird Buyer -Admission after the prepaid vendor line is admitted. ~ 7:15AM
** You may not sell. **
$15 per person at the gate.

One of my favorite gadgets is the Datel DVC 8500 voltage calibrator.
Small, fairly stable, +/- 19999 mV via thumbwheel switches, plus
trimming. They pop up on eBay aperiodically (one currently listed,
going for $31, and recently calibrated -- a deal. Item 3814748987).

You may want to have a look at
http://www.nitehawk.com/sm5bsz/linuxdsp/linrad.htm

This is the Linrad home page
Take the output of your Rx and feed it to the computer sound card.
You will have to do a bit of work getting up to speed on Linux if you
are not already familiar. However, the newer Linux distributions are
becoming better than Windows in terms of usability, in my opinion. The
program itself also takes some work to set up. However, you can use a
relatively low power computer eg 400 MHz PII, which are available
cheaply now as your DSP platform.
This is a very sophisticated package which is designed originally for
144 MHz EME.
If you really want to get into it, you could build the hardware as well

I bought a Fluke 3330B for under $50 -- I was stunned that it was in perfect cal -- I just used it for an article that had a microprocessor controlled power supply -- nice to have the Fluke so that you don't have to play around withthe code or worry about a keyboard. It is a beast, however. I bought a second "parts" unit in case anything goes wrong with the first one.

When you play around with these things you begin to purchase high quality cables and connectors. I didn't know a "Seelback" from a humpback!

The bloody surfboards don't come in any useful formats.

If you are doing SOIC, you can almost do it manhattan style. A lot of the really interesting parts are in TSSOP. Of course, Surfboard have few TSSOP boards, and the ones they do have are just a few pins. Heck, I can somehow cobble an 8 pin TSSOP, what I need help on are the 24 and 28 pin jobs.

I do mean KD1JV. However, I don't think Steve ever wrote anything up. If I recall, he used the TRF4900 which is a "transmitter" - basically a DDS with an amplifier. The 4400 looked a little more interesting to me, same thing, lower frequency. I've been meaning to do something similar for a while now. I had assumed that you needed to operate these parts somewhere near their spec frequency, 900 MHz for the 4900, 450 for the 4400. Steve went right down to 6 meters for his first whack and had no problems.

What is interesting about these is that they are reasonably priced, and the frequency steps are small enough that you are in the neighborhood of a Hz or two after dividing them down to HF, reasonable for a CW rig. They are also easily obtained.

TI also has a series of synthesizer chips, the 2050 and 2052 that seems to be a bit more flexible, but maybe more complicated. All these parts are under five bucks quantity one.

I have to admit, after getting over my shyness over asking AD for samples, the AD parts look a lot more appealing. But I have a few of these TI chips, and I finally got a prototyping board that will work with them, now if I can just get the time to play with them...

I would recommend surfing eBay for a Sony EP9ES. It was among the best
of the standalone DD decoders, and sold for nearly $1K circa 1998.
Because few people use standalone decoders these days, they are
available for a song, no pun intended.

I don't think there's much to be gained by building your own Dolby
decoder. It would involve interfacing a highly-proprietary
preprogrammed DSP chip to a total of six DACs, and then writing user-
interface code on a separate processor to control the whole shooting
match. A lot of tedious work with very little room for innovation,
education, or useful experimentation.

If they can be taken down to HF also, it would be very easy to make a CW tx for 17 - 10 meters with such DDS-PLL chips. Right now that is not so interesting, but by the time we approach the next solar peak (2008+?), there may be many more such chips available also.

Yep, and in smaller packages too! :-) Those mentioned by xpyttl are in
TSSOP packages if I recall correctly: way too small to hand-solder!

Sometimes I am "frustrated" by the huge amount of useful ICs for HAM
homebrewing shipped in ultra-space-saving packages. :-(

TSSOP is easy to solder using the 'drag soldering' technique. I use a
special Metcal system with a hoof tip, but it can be done with ordinary
soldering equipment. Plenty of liquid flux is the secret to success.

I use pretty much the same technique as Leon, without the special equipment.
It does take a little care, and a lot of patience. But it really isn't all
that intimidating. Now, BGA's, those are scary!

3800. 455 kHz CW filter for ICOM

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-14 16:27:27 UTC
From: Jon K Hellan <hellan@acm.org>
Message-ID: <87brkr7z4g.fsf@acm.org>
Source record: 26086
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Hi,

I have an ICOM 707 transceiver which uses 455 kHz filters (FL-52A and FL-53A). I would like to add a CW filter, but ICOM's filters are pretty expensive. I wonder if I could use a 455 kHz filter for a different radio instead. Some mechanical adapation will be necessary, but will they be electrically compatible?

I've found the following link: http://www.qrpproject.de/UK/inradfilt.htm. Here, an alternative filter is suggested for both YAESU FT817 and ICOM IC703. The ICOM uses the same filters as mine, so this would suggest that filters for the YAESU might work in ICOM.

Regards

Jon Kï¿½re - LA4RT

Huh? I have used surfboards to make up all kinds of microphone preamps small
enough to fit into the microphone itself - certainly a very useful format
to have indeed!!

Not everyone is working with 24 and 28 pin IC's.

Beauty (usefulness) is in the eye of the beholder.

Got an Anatomy lab dissection kit yesterday for a snip GBP7 USD10. It contains a decent scalpel, various scissors, tweezers pokers, prodders, jabbers, impalers scrunchers and whatchamacallits. All in surgical stainless steel. I'm thinking twice about donating my body to medical science now though ;-)

Also they had a diagnostic kit at a song (otoscope/opthalmoscope) handy for close inspection. I didn't have a look as my hands were manky and I wouldn't want anything like that prodding about me after it had been in my hands. I'll maybe go in with clean hands on Monday.

I don't think they will work very well, you really need transmission line
transformers wound on suitable cores for diode ring mixers.

Your injection frequency for the LSB mode probably isn't set correctly. You didn't say how your audio sounded. If it is lacking low frequency response, the injection frequency is too far down on the filter slope. This would also account for the lower output power.
I am not familiar with the innards of this rig.....it is possible that this could be corrected through a softkey menu. I am sure that this rig probably has a service menu mode.

=======
Perhaps not suitable for higher RF frequencies ,but these transformers can
be readily used for AF ,for example to provide galvanic separation between
a PC (soundcard) and a radio for operating digital modes like PSK31 etc .

Hi

Does anyone know where I can get a look at the Heathkit SB220 Manuals? I would like to see the schematics on this unit especially interested in the transformer's primary and secondary hook ups.
Any one know a link where I can find the service manual or operators manual?
Thanks
Bob

3816. Jumpy Silver Mica Capacitors ?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-16 14:06:24 UTC
From: skavanagh72nospam@yahoo.ca
Message-ID: <5249fb3f.0405160606.65a3193a@posting.google.com>
Source record: 26002
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design

A year or so ago I was working on a microwave local oscillator (at about 2.5 GHz) multiplied up from a crystal oscillator near 40 MHz. The output was found to jump in frequency by tens or hundreds of Hz many times as the LO chain was warming up. I was able to reduce this jumping by replacing all the dipped silver mica capacitors in the crystal oscillator stage with NP0 ceramics. There is still a bit of jumping which may come from some silver micas which remain in the stage following the crystal oscillator.

I have just been observing the same sort of frequent jumping behaviour (up to a kHz or so at a time) in another local oscillator (output at about 10.5 GHz, phase locked to a crystal oscillator around 100 MHz). I note that this one also has dipped silver mica caps in the crystal oscillator and I wonder if it too would be improved by replacing them with NP0 ceramics.

The capacitors used in both cases are from unknown sources and were probably manufactured in the early 1980's.

Has anyone else experienced this behaviour ?

Steve (VE3SMA)

Steve, I've had several silver micas go weird in 20 odd year old Racal radios that I've fixed, they're second only to Tantalum caps as a cause of faults in those. But at least they don't explode!

Regards
Dan

Not personally, but I believe I've seen it mentioned in one of Doug
DeMaw W1FB's books on QRP transceiver design.

Yes, a long time ago I saw just the same sort of behavior in LC
oscillators using silvered mica caps. Ever since, I haven't trusted
them, and use NPO/C0G instead for frequency control applications.

Cheers,
Tom

Hi folks,

I am auctioning off a distance learning course in Electronics
Engineering. This course is an
extremely throrough way to teach yourself electronics if you are an
amateur and would like to
learn a whole lot more. The link is:

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=4213912610

The course is from the Cleveland Institute of Electronics and includes
basically all of the material, course booklets, and parts you need to
complete the equivalent of an Associate's Degree in EET. I learned a
heck of a lot from the course, but I have graduated and need to free
up space in my small apartment. Thanks for looking!

Cheers,
Trevor de Clercq

Steve,
Although I didn't figure it out at the time, my Knight-Kit Space Spanner
circa 1960 had terrible microphonics - very noisy. I cleaned the entire
chassis & rewired it to no avail. Today I suspect a mica cap, the old
square type, since I heard of same thing this some time ago.

3830. ISO Manual for Telephone Interconnects. Zetron and IDA System 2

I have a similar problem on USB. My receive audio dropped to barely audible, and it sounded like people are talking from within a tin can. Got a friend on air, we compared AM, FM, CW USB and LSB, and I listened to RTTY. Everything received well except USB; LSB was a little off, I think. Transmit was fine (5-8, 5-9). Wrote ICOM, they had 'no ideas for troubleshooting.' Sent it back Friday (5/14) as it's still under warranty.

Will let'cha know what ICOM says!

1.5mH doesn't make them sound very interesting for anything above very
low HF frequencies, if that, and would be too low for AF where 1.5mH
at 1kHz is only about 8 ohms reactance. They might be pretty good for
isolated driving of mosfet gates at a few tens of kHz. You should be
able to find their self-resonant frequency, and my guess is it will be
in the vicinity of 2MHz. You probably don't want to try to use them
above their SRF.

Do you have a manufacturer's part number? Can you look up what they
are recommending them for?

Cheers,
Tom

Do the silver mica caps say "made in china" on them? Are they a light tan
color? If either of these are true chances are you will get a better cap
made from ear wax and tin foil. Somewhere in China there was, and perhaps
still is a factory, that made silver mica caps that change value if you
squeeze them between your fingers and go open if you heat cycle them.

I've never had much trouble with CDE caps.

That may be the secret here. In the past, I've used silver mica caps in a number of applications with positive results. The only problem I've ever seen with good quality ones was a single one in a 40 year old HP amplifier that had become leaky.

If silvered mica caps are so crappy, why did they ever use them in
the first place?

Thanks,
Rich

I keep waiting for someone to come out with a reasonably priced X-ray inspection sytem. (Pace has the XR 3000 for all of $40,000 at the moment!) At the, say, couple thousand dollar point every small business out there would be able to afford one, and used units would show up that amateurs might be able to afford.

Yea! AND, get this, I think I took plates off, or bent some, of the
bandspread cap to reduce its range and calibrated it for 40 M. Every
Saturday morning I'd listen to the same group on SSB talking about their
Collins rigs and inverted Vees.
Wish I still had it and the Knight-Kit crystal set. Had it hooked up to
a loud speaker in my room (course I was in Wood Dale, IL., not too far from
the WBBM and WGN AM transmitters...)

Real mica has to be real old and it sn't aging much in a capacitor because it has been aging for eons and for all pracitcal purposes inert. If mica capacitors are jumpy it must be due to the plating or encapsulation! If there's no clue to the mfg it could be that these jumpy were not manufacutured for your application. JMHO

I recently got two older Icom IC-2N HTs (2 meter) for use in decoding APRS packet radio. Nice radios, but I get less than 10% of packets decoded with either radio. Compared to 100% of packets using my Yaesu VX-2R. I know the problem is not the decoder, but the radio audio, and wondered if there is anything I can do to improve the Icoms.

(And, no, I do not have an oscilloscope.)

>and wondered if there is anything I can do to improve the Icoms.

The first and simplest things I'd suggest are:

- Make sure that you've turned the HT's power-saving receiver mode
off! A lot of HTs save battery power by spending most of their
time with the receiver "asleep", turning the receiver on several
times per second, and checking for the presence of carrier. This
will play merry hob with packet reception, as you'll almost always
lose most of the packet-synchronization preamble.

- Turn the HT's volume level down fairly low. You want to make sure
that the analog signal coming out of the HT isn't clipping
(overdriving the HT's audio output circuitry) and isn't overdriving
the TNC's input circuit. It's usually a good deal easier for a TNC
(hard or soft) to track a low-level audio signal, than it is for it
to track an overdriven high-amplitude signal full of distortion and
intermodulation.

If neither of these helps, then I'd suspect that there's some nasty
noise or distortion, or excessive receive equalization occurring in
the HT's audio circuitry, and that some substantial circuit mods might
be required. These would probably require a schematic, 'scope, and
some audio analysis tools such as an audio spectrum analyzer to figure
out properly.

I was not suggesting that they were crappy. I was suggesting that of
all the high quality ones I have worked with over many years, I've
only seen 1 failure.

His experience may well be due to the fact that his were of unknown
origin and unknown quality.

<< I recently got two older Icom IC-2N HTs (2 meter) for use in decoding APRS packet radio. Nice radios, but I get less than 10% of packets decoded with either radio. >>

Mike-

I agree with Dave's assessment of your problem. My first thought was to turn down the audio level and see if that improved things. Otherwise, check to be sure your +5 KHz switch is off (or on if appropriate).

Back around 1990, I had an IC-3AT and an IC-2AT connected in an experimental dual TheNet node, connecting between a 220 backbone network and local access on Two Meters. I never had a problem like yours.

I'm not familiar with the IC-2N. Could it be a variant of the IC-2A? If not, then it is possible that model had a differently wired earphone jack, with a DC voltage on the shield terminal rather than ground. In that case, there could be a short circuit when connected to a TNC that had its ground also connected to the co-ax shield on an external antenna. I know this could be the case with some Radio Shack handheld radios, but have never encountered it with Icom.

Thanks for all your comments. Since speculation has started here is what I know about the capacitors.

Those used in the 2.5 GHz source are surplus from a company that makes high quality stuff. They were probably procured to a military or space specification but I am not sure. The 10.5 GHz source was manufactured by MA/COM about 20 years ago. All of them are the usual deep maroon (is that the right word ?) to brown colour.

Keep in mind I am being pretty picky. I consider short term frequency jumps of much over 100 Hz to be unsatisfactory - that is 10-40 parts per billion depending on which source is considered. The largest observed jumps are about ten times this. Of course, since these are crystal oscillators, the corresponding capacitance jumps must be much larger, since the crystal should dominate the oscillator stability. I would not consider them "crappy", just not as good as one might be led to expect. I have used capacitors from the same provenance as those in the 2.5 GHz source in LC oscillators at a few MHz with no observed problems. The smooth portion of the warm-up drift is reasonably normal in both cases...only the jumpiness is unusual.

Steve

Thanks for the good advice from both you and Dave Platt. I'll try lowering the volume and see if that has any effect.

There's no power save mode or any +5 KHz switch; the radio is very simple with just a squelch, volume, and transmitting Hi/Lo switch. And the thumbdials for the frequency. I experimented with the Hi/Lo switch just to rule that out too.

I took a look inside the radio and it's all discrete components. The audio even sounds pretty good (to my ears). And I can transmit packets from my Yaesu VX-2R to the Icoms from within my apartment with good decoding.

Can I build a simple filter that removes everything except 1200/2200Hz tones?

Mike

>packets from my Yaesu VX-2R to the Icoms from within my apartment with
>good decoding.

If you can gain short-term access to an oscilloscope, it'd be beneficial to simply watch the waveform coming out of the audio-out jack. Tune to a busy packet frequency (144.390 will usually get you boatloads of APRS packets), slowly turn up the volume control, and find the point at which the audio waveform stops increasing in amplitude and begins exhibiting a flattening-off of the tops and bottoms. At this point, your signal is clipping - you definitely want the volume control turned down below this point. Further reductions may be beneficial if you're accidentally overdriving the TNC's audio input circuitry.

>Can I build a simple filter that removes everything except 1200/2200Hz
>tones?

It's possible, but it's not necessarily trivial. It can be done fairly easily with active electronics (i.e. one op amp and a dozen or so passive parts). Take a look at www.tnc-x.com and pull up the schematic - the receive-audio filter is implemented by U4 and the parts around it.

It can also be done with a strictly passive circuit, requiring no power, but that's a bit more involved, and will probably require some fairly large audio inductors.

What you'll want, in either case, is a bandpass filter which passes roughly 1000 - 2500 Hz, and rolls off both the low and high frequencies on either side of that passband.

A well-designed TNC should already have this sort of bandpass filtering built into its input circuit, I think - adding an outboard filter between radio and TNC ought not to be necessary.

Coming in at the end of this discussion, I'll have to question the observation of the so-called "frequency jump." At 100 PPB we are talking quite serious test equipment hook-ups and a number of different techniques very much uncommon in home workshop practice.

If you are locking the X-band source to a crystal reference, then there is a great deal of this frequency-control subsystem which can be a cause for the "jumps." That can be the sampler or prescaler, the phase detector (assuming it is a form of PLL), the loop filter, and even the power supply rail voltage (affecting the voltage control of the presumed voltage-controlled frequency adjuster circuit). ANY of those can be the culprit in small frequency "jumps." That would include whatever it is you are using to heterodyne with the X-band source to enable frequency measurement.

I'm going to question all those others' claims about "jumpy silver mica capacitors" after about 54 years of having hands-on experience in RF and pulse circuitry. I'm talking primarily the "dipped" coating DMs with some excursions into the molded plastic case axial lead models. I've never had one either open or

shorted and never "jumpy" in value and that includes the full-on military environment testing of temperature, altitude, shock, vibration, etc. A very few were found not quite within the capacity value tolerance and not a single one experienced any "jumping" of value. I've not heard of any such stories from contemporaries in the industry...and I HAVE heard lots of urban-myth stories on other things within all of electronics.

Crystals can also jump. Just look at HP oven oscillators used in the GPS time/frequency references. Very jumpy. A collegue tried 5 oscillators in the GPS time/freq reference and all were jumpy to various degrees. He was noting sub-ppb jumps.

Well, I should point out that I'm not using a regular TNC. I'm using
this: http://www.ringolake.com/pic_proj/zcd/zcdmodem.html

It has worked very well with my little mighty Yaesu VX-2R, just not
with the Icom IC-2N.

Did try the volume this evening...I was only able to decode packets
with the volume at least 3/4ths. And even then it wasn't packets from
the local repeater, but from my Yaesu in the other room.

Mike-

That gets back to the +5KHz question. Have you ever had the frequency of the IC-2N adjusted?

If it is like the IC-2A, there is one master crystal oscillator that sets the receive frequency, and three oscillators that set transmit minus, transmit simplex and transmit plus offsets from the receive oscillator.

If the receive oscillator was off frequency, and you had adjusted a transmit offset oscillator to bring it back on frequency, then the receive frequency would still be off. Try setting the receive frequency 5 KHz higher and lower using the thumbwheel switches, and see if either makes an improvement. That would tell you the radio needs alignment.

I have built numerous VCO's that work as you describe.
A tuned coaxial line is used and the feedback is controlled
by a capacitor. Making the capacitor small will allow harmonic
oscillation, making it small will allow fundamental.

Since you can make say a 9th overtone crystal oscillator,
there is no reason why you can't make a 9th overtone transmission
line resonator oscillator.

That was an initial thought, that, given a flat-gain amp, like a MMIC,
the coupling capacitors reactance would determine what frequency maximum
power would be transfered. The reactance the amplifier I/O impedance
matched the line I/O impedance.

> Since you can make say a 9th overtone crystal oscillator,

I'm thinking I should try a binary weighted series-L shunt-C ladder
network, with varactors for the C. Could switch the varactors into
forward conduction to tune out the end of the line, raising the frequency.

Latest Microwave News describes a nonlinear ceramic (BaZrTiO) thin-film
voltage-tuned capacitor. I've read about articles that use common
ceramic caps as VCO's, even the capacitor-equivalent of magnetic
amplifiers. The advantage of thin films is you can fabricate
voltage-tuned filters, as well as individual caps.

Now if I could just fabricate my own, using basement PCB lithographic
techniques, or my microwave oven to plasma sputter the film.

You may want to look for a free program called RFSIM99 which is an 'S' parameter analysis program using schematic entry. I find it useful, although I haven't tried to load microstrip matching sections yet.

It is fairly intuitive, and I see the microstrip transmission component looks to be reasonably comprehensive.

I particularly like the monte-carlo random component tolerance analysis. It's helped me to make sure my designs will be easy to build and likely to work.

I am sure Ansoft Designer SV is a more powerful program, but for most of the things I do, RFSIM99 is nice.

This mdemless TNC design looks to me as if it might be rather
vulnerable to the presence of high-frequency noise in the audio
signal. It's not using conventional bandpass detection, but is using
a simplified zero-crossing detector. High-frequency audio noise could
cause spurious zero crossings, which the firmware in the onboard PIC
might not be filtering out adequately. The IC-2N may have a "hotter"
receiver section which could be passing through more noise from weaker
packet stations.

First thing I might try would be adding a low-pass RC filter - one or
two stages - with a cutoff frequency of 2500 or 3000 Hz. Adding a
series capacitor to act as a high-pass filter at 800 - 1000 Hz might
also help.

JW-

I have some Avery postcard stock with two 4" X 6" cards per sheet. I've have been meaning to print some QSLs, but haven't gotten around to it. I wonder if there are any templates around for the QSL information? I like the idea of a personalized card for each QSO, rather than hand-printing the information.

Doing it yourself is handy, but the cost may be higher than you think. If you were to have a quantity of cards printed at a print shop, they might cost less per card. There is also the issue of inkjet prints fading over time. Cards from a print shop may eventually fade, but not nearly as fast (unless your printer uses pigment-based ink).

The QSLs I received from my first QSOs 30 years ago are surviving nicely.

Ironically, the newer cards aren't doing nearly as well.

Mostly, the problem seems to have to do with computer-printed report forms and stickers. The ink on dot-matrix ribbons seems to be rather susceptible to fading. And more than one QSL with the report form printed on a mailing label seems to have lost its label.

Ink-jet printing also seems susceptible to damage from moisture. Get a bit of water on it, and who knows what'll come out!

Yes, but the equipment here is up to the task. For the 10.5 GHz case
I am using this source as a receiver LO. A second receiver is
available and both can receive a third source. Both receivers
heterodyne the signal down to audio frequencies where any frequency
steps can be easily detected by ear. The receiver with the M/ACOM LO
jumps (frequency steps) with respect to the third source while the
second receiver does not. A similar scheme was used at 2.5 GHz.

And from qrk:

> Crystals can also jump.

Yes, I have not yet narrowed down the search in the M/ACOM 10.5 GHz
source, but was wondering about the likelihood of the silver mica caps
being the culprit. It has a measured supply voltage sensitivity of
about 50kHz/V (post regulator). The plug-in (not soldered) crystal in
an oven would also seem to be a likely source, particularly as the
jumping seems to improve after warmup (but long after the oven reaches
temperature).

Well, Tom Bruhns is the first one I have run across who has also noted this, so it can't be a very commonly experienced effect. But I am pretty sure about the source of the jumping in the 2.5 GHz source. Each silver mica capacitor replaced made it better (unless the PC board just needed the thermal cycling resulting from a few extra soldering operations).

Steve

Several roll ur own QSL card schemes at URL:
http://ac6v.com/dealers.htm#CRE

But if you use an inkjet printer and run high color density and print large quantities -- you will go broke buying inkjet cartridges.
Tis OK for a few cards.

For large quantities, Tis a lot more economical to use QSL card printers at URL:
http://ac6v.com/dealers.htm#QSL

I like Cheap QSL's (good looking cards)
URL: http://www.cheapqsls.com/
$10.00 a hundred No affiliation -- just a good printer

I've been following those nonlinear ceramics (ie BST) for years. They
don't seem very promising as a tuning diode replacement. The Q is too
low, the tuning range is too restricted, and there are temperature problems.

Not really. If he's working with a 1296 MHz SSB rig, for instance, then
he's not going to be happy with 100 Hz jumps.

Hi guys,

From your vast collective knowledge, please could you recommend a video transmitter with the following characteristics:

* very low power consumption (<70mA), ideally running at below 7.4volts

* small size

* transmits mono audio and colour video

* transmits outside the spectrum used by WiFi (802.11b/g uses 2401-2483 MHz). In practice I guess this means the video tx must use either 800Mhz, 1400Mhz, 2300Mhz or 5800Mhz. It must be legal for use in the UK. What I'm after is a video TX that uses a "quiet" part of the spectrum. 2.4GHz certainly aint quiet (wifi, digital cordless phones, microwaves, AV transmission)!

* available in the UK

* costs less than 150 UK pounds

* comes with a compatible RX which also has very low power consumption.

Many thanks for your help,
Jack

PS
Sorry for sending to so many newsgroups. I've spent bloody ages trying to find a solution but with no luck yet so I'm eager to get as much advice as possible.

>Anyone else roll their own? Tips?

I did my own via some hand-coding in PostScript, sent 'em to a color
laserprinter, printed on the same sort of card stock, and chopped them
apart on a standard paper-cutter.

http://www.radagast.org/~dplatt/hamradio/qsl/ has several variants.

I've used Word or Word Perfect to make one master sheet consisting of 4 qsls on 8 1/2" x 11" landscape. I take that master to Office Max or Office Depot where they can copy the master with a laser printer on card stock and cut the cards as per your specs. You pay for the amount of card stock you use. (I usually get 25 sheets @ 17 cents/sheet.) And you are charged one dollar for each cut they have to make. (The cuts are made with a commercial paper cutter.)

Heterodyning down to an easier-to-use frequency range is an old,
established technique. The problem I see is one of "isolating"
the "jumping," of identifying the "jumps" in terms of time and
occurance (random or with some vague periodicity?).

A substitution method of isolation is necessary to pare down the
number of possibilities of the cause. To get into the parts-per-
billion range of stability, some elaborate measurement systems
need to be used...such as what the NTIS does to verify stability
of frequency sources. Lots of good material on their website for
this sort of thing but the site organization requires some digging
to reach it.

>And from qrk:

If the supply voltage sensitivity is that value, then a 100 Hz to 1 KHz
deviation would be in the neighborhood of 2 to 20 mV supply rail
change. If, for any reason, the supply rail changes, that could cause
the frequency jumps.

>Each silver mica capacitor replaced made it better (unless the PC
>board just needed the thermal cycling resulting from a few extra
>soldering operations).

The extra stress of capacitor replacement might have affected
some other "jump" cause, thus masking that by what you thought
might be the culprit.

I'm not doing any personal accusation thing here, just trying to get
some isolation on exactly where the possible cause might be other
than "jumpy silver micas." I have encountered such weird things as
exposed copper PCB traces gathering oxides over time, such oxides
actually bridging the supposed isulating gap between traces and
causing very minute fluctuations down in the 1 mV region with a DC
bias between conductors. On another case, of using "stiff" wire
jumpers (which were NOT entirely copper but plated nickel) in a
rotary switch assembly, the resulting temperature-sensitive voltage
(like a thermocouple junction) caused an out-of-scale drift in a
supposedly-simple meter circuit. Visual inspection would have
passed it no problem but a magnet showed an attraction to the
jumper wires indicating it was not copper. Even if the jumpers were
soldered in with good visible junctions, the thermal EMF from
dissimilar metals was enough to throw off calibration over the mild
industrial-grade temperature rating.

I'm not saying either of those conditions might be present with your
problem, just trying to illustrate weirdness that can happen. For
safety sake (of mind), I coat circuit traces around sensitive areas
such as oscillators, multivibrators, low-level DC and AC circuits with
some petroleum-based varnish (such as McCloskey's "Gym Seal")
after doing some simple, non-plated circuit board assemblies having
bare etched copper traces.

Having done a fair amount of L-, S-, and C-band RF work (that's 1 to
to 8 GHz for civilians who never bothered with the "new" military
alphabetic bands and preferred the ancient letters), and using the
heterodyning technique to bring them down to measureable regions,
I've encountered lots of different causes for oscillator instability that

ranges from supposedly-stable DC supply rails to the oxide problem mentioned to odd things such as magnetic coupling from AC cords to various ferrites used for external frequency control. Anything is suspect and, at the tolerances you need, aren't given as standard in texts.

I'd start with giving the supply rails a workup down to a gnat's eyelash on stability, both at DC and low AC. Then I'd try out the local environment, the bench, even to trying to raise the oscillator by supporting it on a small piece of plywood (might be some power wiring under the bench surface). Then it is small spritzes of cooling spray, very small in small areas. Even banging on the support with a tack hammer or equivalent weight for minor shock and vibration. Then it would evolve into going "split personality" and trying to look at the assembly critically as if you were another person just finding out about a problem and not pre-judging what "might" be happening.

Now, it MIGHT be a faulty component made by someone else, including the crystal unit, but pre-judging a "fault" is not a good way to start. I've had contemporaries relate lots of urban myth stories (like electrolytics "always go bad with time" but don't) about "cause" but those aren't always truisms. The approach has to be analytical, one of isolating all the factors that test good in order to narrow the source area to a very small one. Easy that ain't. Perseverance is an absolute must when pushing the envelope.

I have yet to discover a "jumpy silver mica capacitor" but I might find one even with over a half century of playing RF games with parts and going from the kind of micas found in old ARC-5 radios to sampling PLL loop stabilized sources using DM30s in the loop filter (but had one unidentifiable-cause varactor that was replaced but never examined in detail later).

>Steve (VE3SMA)
in the crystal oscillator business silver mica capacitors were known for
scintillation . The potting compound of sm capacitors was ofteen the
cause of temperature coefficient drift. Scintilation was probably due to
delamination of the mica.
Modern NPO ceramic are probably better particularly unencapsulated
surface mount.

3885. DC saturation for ferrite cores

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-20 21:29:02 UTC
From: J M Noeding <la8ak@online.no>
Message-ID: <og8qa0d4tj34cseic73s5fa9hf1lfo1k6o@4ax.com>
Source record: 25988

Hi
have noted the following measurement (from LA7MI) forAmidon
FB43-4301, and wonder if someone knows more available data for actual
ferrite- and iron-powder cores to be used in transmitters?

For a Amidon FB43-4301 the inductance drops by 50% for 1.2At. 3At for
75% reduction. One should keep the DC-current below the value of 0.5A
to keep the reduction below 0.5. In the example above this rule is
used, but the best is to use push-pull arrangement and the DC
magnitation is kept to a minimum level. The inductance reduction is
stored and the effect is called remanence, cores used for direct
current should have air-gap

Will write a page - http://www.noding.com/pictures/la8ak/n12.htm for
constructing RF power amplifier based on an article written by LA7MI
and distributed to a local London radio club in 1992

Use the 2.4Ghz video system from Radio Shack. Wi-Fi is a spread spectrum signal and will not interfere with the video. The Radio Shack system won't cause a problem with the Wi-Fi.

> Anyone else roll their own? Tips?

I make my own using WordStar 6.0 running in a DOS box under OS/2.
Print'em on an HP LJ III printer.
Artwork? Luckily I live in a "rectangular" state. HI!HI!

But, I _do_ make'em specific for use. I.e, a stack of 6M cards, a
stack of 2M cards, a stack of OMISS Net cards, a stack of Mobile
cards, und so weiter...

3889. Re: pulse transformers

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-21 00:06:22 UTC
From: J M Noeding <la8ak@online.no>
Message-ID: <a7aqa09k98n9p8296e75scr7rj88vlpb26@4ax.com>
Source record: 25989

They might be useful in the range 20-200kHz with 50 ohm, see the notes
on http://www.noding.com/pictures/la8ak/n12.htm where it is some notes
to describe inductance requirements for toroid transformers
(all text is not written, tried to use word, but it was a disaster, so
I have to wait and look for another html editor to finish the page)

Many of us have already confirmed that pulse transformers may work
perfectly well in linear circuits, so I wonder if the comments that
they shouldn't is only based on lack of practical experience, any
ferrite transformers may even be used as memory for old type computers

I doubt that many people would notice ppb changes and jumps. This takes a bit of patience and ruling out bad test equipment/setup to observe this phenomena.

Source record: 25975

Anybody ever see a D cell flashlight battery with a poor connection
inside?
I had a flashlight that was giving me fits. The light would always
fade out or quite at the most inopportune time. A shake or bang would
sometimes get it working again.
I cleaned battery connections and every other connection inside the
flashlight. No help.

Finally when I had the batteries out I happened to shake one and it
sounded like liquid inside. There was a rattle in it! It was a
duracell alkaline. The battery still had good voltage but an
intermittent connection inside.

New batteries solved the problem. Anyone else ever hear of a problem
like that with D cells?

Source record: 25976

I was just wondering... with all the excitment that the shortwave (listening) community seems to be having down on HF with digital radio Mondiale (DRM), have people been experimenting with similar digital voice encoding/decoding on 2m? It seems as though DRM-style radio would pass through many current repeaters without difficulty (being spectrally efficient) and be especially valuable in handitalkies that don't yet typically have DSP processing to clean up the audio.

I just did an FFT on a step-pulse on a diode-switched, binary weighted
LC ladder. Came out as I expected. Problem is the high-frequency
resonances exist on when the low frequency sections are not shorted.
Which will make transistor oscillator design interesting, if I don't use
a 50 ohm MMIC.

The latest Microwave News article showed the Q as being better than
varactor Q's, of under 10, IIRC.

It has certainly been noticed by many more people than Tom.

The word "scintillation" rang a very faint bell, and Google found a
reference at:
http://www.seas.gwu.edu/~ecelabs/appnotes/PDF/refdata/page2.pdf

These scanned pages from an unknown reference book define:
"Scintillation: minute and rapid fluctuations of capacitance, formerly
exhibited by silvered mica and silvered ceramic types [of capacitors]
but overcome by modern manufacturing techniques."

Well, maybe not *totally* overcome...

This explains why we only tend to hear about the problem in very old
capacitors (probably WW2 era) or in critical applications such as
precision oscillators.

The reference to silvered-ceramic capacitors is interesting. Evidently
that scintillation problem was "overcome" more completely than for
silvered-mica, which is why NP0 ceramic are now the capacitors of choice
for oscillator applications.

Hi,

Does anyone here know how I can determine Zin of 2N3866 at 150MHz, Output is matched to 140R for 200mW.

I have an RF sig gen, Spectrum analyzer, RF power meter, 300MHz scope and VSWR brdige with built-in detector.

Also, anyone know of a good site that explains RF test methods. (Measuring filter response etc)

Thanks

Regards
David

Yes... but I had the problem on one or two occasions with 9v
batteries---Wallgreen store brand. Considering the large number of
batteries I used the issue is a minor one in my instance. BTW, those
Wallgreen batteries are a good deal, especially when they are on sale.

I had one once which seemed to just have very high internal
resistance. It measured fine for voltage using a high impedance
voltmeter, but wouldn't get the bulb much above a dull glow. There was
no rattle to it, however, and I only solved the problem by throwing it
away.

The bridge of Wheatstone, or equivalent.
I always determine Zin too in the simulator Electronic Workbench, before I go to build
it in real.
But you can do it directly in real.
Connect a variable resistor between output generator and input 2N3866.
Add an 2 Chan. Scope, output generator to Chan 1, input 2N3866 to Chan 2.
A broadband Oscilloscope is not needed, it is the amplitude that is going to be
measured.
Turn the potentiometer until you have half the amplitude of Chan 1, on Chan 2.
Now the variable resistor equals Zin.
Power off, losen variable resistor, and measure it with your Ohm meter.
It tells you the impedance @ generator frequency.
1 Chan. Scope can do the job, you keep the amplitude of the generator in mind,
turn the potentiometer until you have half the amplitude at input 2N3866.
Use 10 :1 probes, good luck !
Source of information about RF test methods, the book Test equipment for the radio amateur RSGB author Clive Smith, not the one of the Smith Diagram, hi
!
On the internet, Google finds everything, you have to sort out things, and specify
well.
One serious source is the Agilent homepage. (Hewlett Packard)
The idea how to measure Zin comes from a course Electronics by Dirksen in Dutch.
"RF measurements, the best keeped secrets of Electronics" statement by me.
Greetings... Bas Viel.

in the crystal oscillator business silver mica capacitors were known for
scintillation . The potting compound of silvered mica capacitors was
often the cause of temperature coefficient drift. Scintilation was

probably due to delamination of the mica.
There are 2 types of mica caps cleaved mica and compressed? which powdered the mica and then re-formed. Im not sure about their relative scintillation .
Modern NPO ceramic are probably better particularly un-encapsulated surface mount.
Note that I would design an overtone crystal oscillator with only enough reactance to remove the manufacturing tolerance. This reactance does not have to be capacitative could be inductive capacitative reactance could alternatively be a varicap then the problem would be a clean varicap supply.
Note crystals can do strange things, the jumps described are too small for unwanted modes but there is the well known (to TCXO designers) band breaks these are small frequency jumps that occur at exact temperatures and are due to minor modes passing through the major mode frequency at a particular temperature. This is what limits TCXO performance. OCXO makers make sure that the set temperature is not on a bandbreak.

The musical instrument analogue replicates a delay line.
A delay line oscillator can be induced to oscillate over +-180 degrees
if the overall gain is >1. A multimode delay line oscillator can be
achieved by introducing a peaked gain response at the required overtone.
Alternatively with more than 360 degrees phase shift the oscillation
which cannot change frequency instantaneously can be induced by
continuously increasing phase and jumping from 360 to 0 degrees to sweep
over multimodes.

Hello all.
I have just taken receipt of a Yaesu FT-767GX and there are a few bits I need for it and wondered if anyone can help me with these:
One of the rubber grip covers on the small rotary knobs is missing ?
The rubber grip band around the main rotary channel selector is snapped ?
The 4x rubber feet on the base of the unit are missing ?
The 4x rubber feet (??) on the left hand side of the unit are missing ?
The 3x flaps that cover the holes, where the additional band units fit, are missing ?

Any information at all will be greatly received

Check the Yaesu parts distributor/source (for current models) in the UK.

MANY of the identical parts you mentioned (e.g. bumpers, rubber feet) are
used on other current production Yaesu radios .. and sometimes appear on
Kenwood models with a bit of styling difference.

Source record: 25860

My wife recently had a defibrillator implanted. The folks that manufactured it kindly sent her an email discussing the varoius bands and field strengths it had been tested against E field and H field). She is concerned about exposure to RF both from our mobile VHF and HF operations, and from the un-shielded multi-gigahertz processors in her lab. We would like to come up with an absolute (not relative) field strength meter that we can use to evaluate field strengths (mainly E field) at various frequencies. I could not find anything on Google.

I can cobble something together wirh an antenna, a tuned front end, a detector, and a peak sampler, but how to calibrate it?

Any suggestions?

Hi Ed,
I dont think you can, not without accesss to the proper gear in a RF shielded room (anechoic chamber?). But, and this is an educated guess, the defibrillator would be constructed to withstand fairy massive RF fields - ie, if you lived at the base of a 100Kw TV/ tranmitter. The only practical thing I can suggest is, as most of these devices can be monitered via an external pod to check operation, get your heart specialist to have his monitoring gear on it while you fire up HF/VHF whatever gear - you might have to do a bit of smooth talking, but what other option is there......

I have a friend who is in a similar position, he was a TV service tech and was told not to work on the back of TV' s because of the radiation from the line output stage - sounds a bit like bullshit, but then no manufacturer is EVER going to say its safe to do this as it would expose them to litigation if it didnt - sort of like dont ask the government for pernmission to do anything as they will always cover their backs and say no.

73 de VK3BFA Andrew.

PS - hope your wife is ok, at least she knows if anything happens it will kick in and do a "cold restart"

First of all I'll editorialize by saying this is a paranoid fear unless she frequently travels to areas of very high RF field intensity. Secondly, a 'wearable' instrument will be a compromise, at best. A real spectrum analyzer with a calibrated antenna is what you need for 'accurate' frequency-dependent measurements.
End of editorial.

The simplest way I can think of to do this job is to use the Analog Devices 8307 log detector IC. This chip has an accurate 90 dB measurement range that goes down into the microvolt region and operates to over 1Ghz. If you built a series of these detectors, each one with a broad bandpass filter front-end for the appropriate frequency range, then you could measure all the log output DC voltages with a PIC processor and light up LED indicators when a threshold limit is exceeded. As an embellishment, you might arrange a set of, say, 6 bar-graph LED modules oriented in a vertical position side-by-side with each other. This would provide a crude spectrum analyzer display.

Message-ID: <ke5sc.3396$sr3.83938@news20.bellglobal.com>
Source record: 25865

Recently my tower was hit by lightning. All my ham gear survived except one. Since I forgot to unplug my Amp Supply LK-500ZB Linear Amp from the AC power mains, the lightning found a nice way in.. (The rest of my ham gear was disconnected from the power mains and the antenna)

I wasn't sure whether that amp was affected. But when I turned it on the plate voltage was about half the normal value and the tubes were half as bright.

What is the best way to troubleshoot and repair an amp that was damaged by lightning NOT through the antenna BUT through the AC power mains?

What components will likely need to be replaced? Just the caps? What about the transformer?

Is it worth repairing in the first place?

Transformer, diodes, caps are all subject to damage.

I once had a transformer damaged by a nearby strike. I decided to repair it since it was a multi winding jog that would have been hard to replace. I unwound and counted turns, measuring the wire size for each winding. This was an old style transformer with each layer, neatly flat wound on a fresh layer of paper. Everything looked fine till I got to the very first turn on the bottom winding.

It had been started sloppily, diagonally, and where it passed under other turns, the insulation was burned through. This few turn short lowered the output voltage of all the windings and after a few seconds, blew the primary fuse.

3930. Bi-directional amplifiers

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-23 18:32:59 UTC
From: farhan@phonestack.com
Message-ID: <fcc11bcf.0405231032.1bd1187d@posting.google.com>
Source record: 25867

are there any resources available on design of bidirectional amps on the net?
i have read the few paragraphs in SSD and EMRFD. I am looking for some better material.
In particular, I have the following questions:
1) consider that we have two broad-band amps based on a single npn transistor with a Feedback resistor of Rf and emitter degeneration of Re. consider, further, that we simply connect them back to back and power one or the other, depending upon with direction you might want to amplify. Now, what is the total feedback resistance? is it Rf or Rf/2 (the Rf is between the inputs and the outputs and they are cross coupled, paralleling Rf resistors.
2) Suppose that the output load of a bidirectional amplifier is RL and resistor from collector to Vcc is Rc. Now, does Rc have to same as RL? I guess this is required for best power transfer. But, when the amplifier is amplifying in the opposite direction, then the amp input is paralleled by the Rc. Thus, won't the input impedance of the amp drop by two?
3) Will substituting a pi type attentuator for the load and feeding the input in the opposite direction through the same attenuator solve the problem?

So I went to the Belton, TX hamfest yesterday, and picked up a few things ...

But I saw a number of speaker boxes that people were asking as much as $70 for ... why would somebody pay this much for a speaker box? I just don't get it.

It's just a box with a speaker in it. It's about the easiest thing in the world to make yourself, or you could pick up one that was used in something like a police car for around $10 (I saw some of those too.) Or you could use one from a computer speaker (though the $3 models are probably too crappy even for ham radio use.)

Do people want something that matches their radio equipment? Are they collectors? Am I understimating the quality needed to accurately reproduce a 800 hz CW signal or a SSB conversation? :)

Source record: 25871

I don't know the threshold specs involved, but you can crudely estimate field strength if you know transmitter power. The "impedance" of free space / air is 377 ohms. Thus the ratio of RF field voltage and current will be fixed and related to the power density - unless the field is distorted.

As another crude approximation, assume that (unless you know a radiation pattern) that the unwanted signal's power is equally distributed over a sphere or maybe a hemisphere.

The above will allow you to compute a crude approximation of field strength.

The FCC requires hams to make these calculations with transmitters above certain power thresholds.

How close does this come to the stated "safe" field strengths? I certainly wouldn't want to come as close as 20 dB (10 times voltage) to the stated thresholds.

TV/FM broadcasting stations have very little field strength directly under their tall towers. All broadcasting stations are not allowed to exceed certain field strengths on the ground outside their fenced compounds. The TV/FM stations in a hilltop residential area in Portland, OR, had to greatly increase their tower heights when this rule came into effect.

Not quite.
The delay line can be multioctave and the phase slope will be
proportional the the delay. It may go through many 360 deg phase
rotations over its bandwidth.
An amplifier with much shallower phase slope can still have sufficient
selectivity to determine which particular 360 deg rotation is
oscillated. This has been done successfully with PAL bulk acoustic delay
lines.
The following is more contentious but I think it will work
>
>> Alternatively with more than 360 degrees phase shift the oscillation
>> which cannot change frequency instantaneously can be induced by
>> continuously increasing phase and jumping from 360 to 0 degrees to sweep

>
>Wha? Could you expand on that?
Not a lot. progressively changing phase with varicaps cannot carry on
but the circuit does not know the difference between 360deg and 0 deg.
Goniometers? used to do this for direction finding.
Can also be done with mixers but that is more of a circular argument.

3935. DC saturation for ferrite cores

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-23 22:07:27 UTC
From: J M Noeding <la8ak@online.no>
Message-ID: <aph1b0tkt0n7njhpcsl46o0f3sn74rd79d@4ax.com>
Source record: 25873

Reposted due to changed URL

Hi
have noted the following measurement (from LA7MI) forAmidon
FB43-4301, and wonder if someone knows more available data for actual
ferrite- and iron-powder cores to be used in transmitters?

For a Amidon FB43-4301 the inductance drops by 50% for 1.2At. 3At for
75% reduction. One should keep the DC-current below the value of 0.5A
to keep the reduction below 0.5. In the example above this rule is
used, but the best is to use push-pull arrangement and the DC
magnitation is kept to a minimum level. The inductance reduction is
stored and the effect is called remanence, cores used for direct
current should have air-gap

Will write a page - http://www.noding.com/la8ak/12345/n12.htm (changed
URL) for constructing RF power amplifier based on an article written
by LA7MI and distributed to a local London radio club in 1992

well, it is so nice to inform about my own site, although it has
nothing to do with the request, neither does your reply

A quick calculation for a tuned circuit gave the results of a single
circuitfilter covering 500-1793kHz. Not quite as sharp as requested,
the coil turn calculation might have been right, but what does it
help?

1. Yup they are overpriced. Never understimate peoples desire to
overpay for something. Remember Hagen Dasz ice cream?

2. Lotsa coffee today? ;^) just kidding of course...

Rob,

Well, the first thing would be a visual inspection of the top and bottom sides of the chassis, with the power cord unplugged of course. My guess is that one or more diodes has opened/shorted. An ohmeter check will confirm that, same for the electrolytics. Voltage checks of the transformer will tell if it has obvious damage.

Having said that, it would be best to replace all the diodes and rectifiers and anything else with physical or electrical problems. My experience with servicing gear that has taken a lightning strike or severe surge, is that there are failed and stressed components. Some that were stressed might fail in the near future. I used to fix TVs that had such misfortune, but after 2-3 repairs over 6 months, it was obvious that continued repairs were beyond the point of diminishing returns.

Hope it works out for you.

73s,

Evan

I have had a huge problem with alkalines stored in the refrigerator. They work well after warming back up to room temp as would be expected. Then about three days later they just open circuit!!! Have had this problem so many times that I just buy smaller quantities of batteries now. Used to buy them by the case, and keep refrigerated to increase shelf life.

Rob, you may have answered your question...you say the tubes are HALF as bright..and the plate voltage is HALF of what its supposed to be? Does it normally run on 220-240 volts? I suspect a half side open or damaged pole pig transformer. The amplifier might be fine.....

The phase slope is proportional to the delay. When I think of phase
slope, I think of inductance or capacitance, reactance based phase shift.

> An amplifier with much shallower phase slope

An amplifier with broad bandwidth, having the real, resistive impedance
greater than the reactive impedance?

can still have sufficient
> selectivity to determine which particular 360 deg rotation is

> lines.

I've played around with ring oscillators made from 3 (or more)
transistors, 3 FETs and my favorite, 3 CMOS unbuffered inverter gates. I
find I can tune these sine-wave ring oscillators between 8 and 20 : 1
range, by changing the bias gate voltage and source current. Perhaps
more, after I try a few tricks. 20:1 isn't bad, but I don't see why I
shouldn't be able to get 100,000:1 out of a transconductance-tuned phase
shift oscillator. I guess you'd say these have a very shallow "phase
slope".

I was hoping to use them as a wide-band tuned circuit, by setting the
gain just under the oscillation point. But I found they are very
sensitive to harmonics.

I can bet a delay line oscillator is going to have this same problem then?

I've tried several ways to make a clean wide-range sine-wave oscillator
and regenerative variable tuned circuit.

>selector)

I have used for LF a parallel resonant circuit followed by a
(Darlington) emitter follower driving the 50 ohm line to the receiver.
Assuming hFE=100 for each transistor, the resonant circuit loading is
about 500 kohm, thus the loading is quite small. Since the antenna was
short compared to the wavelength and thus highly capacitive, a small
10-100 pF capacitor was used to connect to the hot side of the
resonant circuit.

Although the voltage gain is only 1, it works surprisingly well due to
the large (natural and artificial) field strengths in the LF and lower
MF bands.

When using some processor controlled receiver, it is a good idea to
move the preselector (and hence the antenna connection) as far as
possible from the receiver and connect them with a shielded cable, to
prevent the receiver processor radiation from entering the high
impedance antenna connection. A 1-2 m separation helps a lot, without
making it too uncomfortable to operate.

Is the radio aligned properly? It's easy to check but if it's out of
alignment, it needs to go to a radio shop to be fixed since proper
calibration tools are needed.

To hear if it's aligned right:
- In AM mode, tune to a time station, such as CHU or WWV.
- Now listen to the station in both LSB and USB modes. Is the sound of the
clock tick the same, or close? If so the rig is aligned properly. If they
don't sound the same, the rig is out of alignment.

Thanks for the post. I am using 240 vots to power the amp. (Any self respecting ham would!)

Yes, I think the transformer may be gone. Like most BIG heavy transformers for HF amps, it will likely be costly to replace the transformer. But I may give it a go.

Ca you explain what you mean by a "damaged pole pig transformer". I have never heard of the term "pole pig"

But after I replace the transformer, I am worried that I may end damaging the new transformer if another component has failed or is close to failure. (e.g. a AC Filter cap or diode).
Is this a realistic fear?

Rob

>Rf/2 (the Rf is between the inputs and the outputs and they are cross
>coupled, paralleling Rf resistors.

Analytically model it.

You are going to have to measure the OFF transistor characteristics
yourself since few parameters other than ESD (Electro-Static
Discharge) are given on datasheets.

But...the "off" transistor might get turned partly on by the other,
"on" amplifier output signal.

>2) Suppose that the output load of a bidirectional amplifier is RL and
>resistor from collector to Vcc is Rc. Now, does Rc have to same as RL?
>I guess this is required for best power transfer. But, when the
>amplifier is amplifying in the opposite direction, then the amp input

>drop by two?

Yes and no. :-)

>3) Will substituting a pi type attentuator for the load and feeding
>the input in the opposite direction through the same attenuator solve
>the problem?

A very few bidirectional amplifiers have been built at RF, all based
on using wideband "hybrid" transformer coupling to a line, both of
them "on." The amount of amplification is limited to just less than

the best directivity of the transformer network (connected as a directional coupler)...and the relative phase shift.

"Directivity" is the relative difference (usually expressed in db) between forward and reverse direction coupling.

The limiting problem in "hybrid" transformers is the resulting phase shifts over any frequency range. That's a separate problem which can be identified, measured, and used to model the repeater amplifier. The reason such types of bidirectional amplifiers are NOT production items is: (1) Need; (2) Ability to control the phase shift over quantity.

About the only source I know of for bidirectional amplifiers, besides the telephone industry (begun before 1920), is VHF-UHF coaxial cable TV service which has "up and down" path communication, both from the "head end" and to the "head end" (for subscriber signalling for such things as pay-per-view showings or for Internet broadband access).

When the radios were new you could by matching factory speakers for about
ten to twenty dollars and most hams being frugal used what they had on hand.
Now that many of those same radios are "collectable" there are as many
speakers around as people want. Supply low price is high, just like crude
oil. I saw the speakers as I was there .

hi there..

does anyone know where I can get hold of a quantity of MOTOROLA 2n4427's??
must be Motorola because other makes just don't work in the crt I am using!!

willing to take ex equipment if necessary..looking for quite a few but will
take ant amount..cash waiting..

thanks simon g0zen

3958. Re: Problems with LSB on IC706MKII

Minor problem with the alignment scenario. There is NO ALIGNMENT for the
carrier oscillators. They come from a DDS chip controlled by the uPC.

Rob..a "pole pig" is the transformer the power company has hanging on the pole or underground. Typically the primary is between 6.8KV and 16KV. The secondary is 120--0--120 volts AC. If you lost one leg of the transformer you get only 120 volts. If the power comapny bridged BOTH leads to one 120 leg..everything in the house on 120 works fine..but the 220-240 stuff either gets ZERO or half voltage. CHeck the outlet for TWO 120 legs (to neutral) and 240 between them. It's VERY suspicious that the tubes glow half bright AND the B+ is HALF what it should be. Does the Amp use seperate filament and B+ transformers?

|But I saw a number of speaker boxes that people were asking as much as
|$70 for ... why would somebody pay this much for a speaker box? I
|just don't get it.
|
|It's just a box with a speaker in it. It's about the easiest thing in
|the world to make yourself, or you could pick up one that was used in
|something like a police car for around $10 (I saw some of those too.)
|Or you could use one from a computer speaker (though the $3 models are
|probably too crappy even for ham radio use.)
|
|Do people want something that matches their radio equipment? Are they
|collectors? Am I understimating the quality needed to accurately
|reproduce a 800 hz CW signal or a SSB conversation? :)

Apparently not according to the Parts Express catalog I received in
today's mail.

Audiophiles have ears so good that they seem to be willing to spend
$100 per foot for copper wire. (No, that's not a typo). Of course
this is "special" wire whose properties include allowing each
frequency to find its own path of least resistance.

This seems to be important even when there is only one frequency (60
Hz) involved, because the same "patented technology" allows
"incredibly fast and accurate transfer of power, blah, blah..." in a 6
foot power cord that can be had for only $492. At least it has
connectors on it, the $100/foot stuff just has spade lugs on the ends
(gold-plated of course).

For some laughs see:

http://www.soundstringcable.com/ss_product.html

It's refreshing to see that they were thoughful enough to print arrows
on the cable jacket so the electrons don't become confused and travel
in the wrong direction. This ensures uniform current and signal flow
to and from all components.

>
> http://www.rexresearch.com/tate/tate.htm#radio

"In studying several smaller earthquakes from 1985-1987, it appeared that the larger the earthquake, the larger and sooner the precursors appeared. The 6.0 earthquake of April 24, 1984 was preceded by a radio depression 6 days before the shock. The Loma Prieta Earthquake of about 7.0 magnitude was preceded by a much greater radio depression 60 days before. A 7.0 magnitude quake is 10 times greater than a 6.0. The 60-day precursor time for the 7.0 earthquake was 10 times the precursor time for the 6.0 earthquake. More data is needed to clarify this relationship."

He may really have something here, but, absent other evidence, how can you prove correlations between events six days apart, much less 60? Further, there is no indication of where the quakes will occur. Assuming signal levels are depressed, it should be possible to monitor signal levels from several regional broadcast stations from several locations, which might help pinpoint the source of the absorption (assuming that's what it is). His claimed accuracy of 70% is only significant if it is possible to designate the area(s) in which tectonic events are pending. The seismic situation in California would probably allow that much "accuracy" through random predictions that an earthquake is about to occur.

The Schlumberger brothers pioneered modern oil-reservoir location in the 1930s by measuring ground resistance during controlled underground explosions. I believe similar methods have been used to try to detect earthquakes. The problem with this method is, you have to cover the ground with closely spaced sensors. That's hard to do in the highly populated earthquake zones of California.

The LM373 was a whole IF strip, a variable gain stage and then a fixed gain
stage feeding the detector. The detector itself is relatively simple.

A "Gilbert Cell" mixer can be a multi-mode detector. Obviously, it's
a product detector for SSB and CW. But put the incoming signal through
a limiter and use that as the "BFO" input and you've got an AM detector
(while the 373 has a separate AM detector, the application notes even
suggest this scheme). Limit the incoming signal, and then feed it
through a suitable phase shifter into the "BFO" input, and you've got an
FM detector.

"Gilbert Cell" mixers show up in plenty of places. The MC1330 AM detector,
and all kinds of FM detector ICs (where they are used as quadrature
detectors, as I describe above)

But I suspect at this late a date, an IC designed to be a multi-mode
detector or IF is realtively rare. There is not much demand for it.
So you have to create the function yourself.

I'm looking for a small handful of ICS501 (http://www.icst.com/) clock multiplier chips to complete a couple of "Montreal Fox" boards (http://www.qsl.net/ve2emm/pic-projects/mfox/mfx501-e.html) for a friend.

Before I try to fast-talk a distributor or the manufacturer out of some samples, does anybody have any of these sitting around, or know of a catalog distributor in the US that may carry them? I'll be happy to pay a reasonable price for two to five of them.

Thanks.

Its "tripping" Mike ? Ive studied the schematics and its a little beyond
me, normally |I can suss most faults out but this one is a right pig. I
have totally disconnected the PSU from the rest of the radio and on switch
on it will just sit there and produce 13.5 and 24v but you put a load on the
24v output and it seems to trip and you have to disconnect the mains and
leave it for a while or discharge the caps until it will work again. In the
rig, with it all wired correctly, you wind up the power and again it trips
and you have to leave it to "reset" ???
Can anyone shed any light ?
If anyone wishes me to send them a file of the PSU schematic then please let
me know.
Thanks.

3980. Non-directional tracking solution?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-26 06:01:34 UTC
From: washed_phenom@hotmail.com
Message-ID: <f8d01f7.0405252201.33fb4ee3@posting.google.com>

Hello,

I'm not certain this is the appropriate newsgroup for this question, but if it isn't, I'd appreciate any referrals to other forums.

In many posts dealing with "foxhunts" and radio tracking situations, I hear directional antennas discussed, or triangulation via a moving receiver. But what are the relevant parameters if the receiving stations are fixed?

Partly for the fun of it, and also for practical uses, I'd like to design a receiving system whereby a small transmitter could be located. This would not technically be a "tracking" situation, since the transmitter would not always be on. I'm imagining something like a garage door opener, where pushing the button can send a brief (but very strong if necessary - this may have power implications?) signal.

The reason I ask about the non-directional solution is because I have access to a plot of land approx. 300 x 300 feet square, with no restrictions on building antennas on the four corners of the property. I'm guessing such a system could be more accurate than a directional system at a given power level, but the technical aspects of the situation are beyond me.

I am a mathematician by trade, but know a smattering of electronics. It would seem, at least in theory, that the relevant parameters here are the distances between the 3-4 antennas (would a 4th help?), and the strength and frequency of the signal. I also realize that some processing of the signal would need to be done at the receiving end. Perhaps the triangulation can be handled by software?

Any advice, direction, URLs, or discussion is much appreciated.

Some wannabees even use more powerful transmitters than yours.

Here's Magic and Energy FM in Ireland.

http://www.magic105.net/techtalk.html

Their target area is Belfast, N. Ireland, around 65 miles away. The
sheep in between are just a bonus.

With their directional array they also have listeners in parts of
Scotland!

Check out their picture links.

Accurate signal strength measurements are surprisingly difficult.
Ground reflections can combine to to double the signal strength,
or nearly cancel it out. Hams and broadcasters often use the term
"picket fencing" to describe the rapid fluctuations in signal strength
that occurs with fixed to mobile signal paths.

Not that your task is impossible, just hard. Perhaps a sufficient number
of signals can be simultaneously processed to statistically reduce the
signal combination/cancellation effect to an acceptable error.

Do you have any frequency ranges in mind? A VHF system would be vastly different in size than shortwave for example.

Doing it by carrier phase would be better, if you could arrange a phase
reference. With hard-mounted receivers (or with a 2nd transmitter in a
known location) you can broadcast a time reference and do a reverse-GPS

sorta thing.

The higher the carrier the better the measurement, but with a lot 100 meters on a side you probably also want to send some sort of time reference (you do get to design the transmitter as well, right?).

3988. How determine pin-outs of car radio?

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-27 03:07:23 UTC
From: mcalhoun@ksu.edu
Message-ID: <c93m1b$58l@unix2.cc.ksu.edu>
Source record: 25924

I'm looking for suggestions (preferably other than "Trace the internal wiring, Idiot!" or "Next time, buy a radio with a manual, Idiot!) on how to determine the pin-outs of a Delco AM/FM radio "about 10 years old" that came with NO manual and has NO identification other than MTD-1316 stamped into the metal on the rear.

On the rear, in addition to the standard antenna jack, there is one 13-pin recessed (mostly?) male connector (I do NOT have the matching connector) for which (I'm hoping) someone will recognize the pin-outs. If <=> represents a horizontal flat "pin", <o> represents a slight dimple (but NOT a hole) in the plastic which holds the <=> pins, <0> represents an actual hole which goes through the plastic, and everything else represents the shell and keying plastic, the plug kinda looks like this:

```
__________________
/ = = = | 0 | = = = \
| o o o o o o o |
| = = = | = | = = = |
+-------------------+
```

I'm NOT going to try to "draw" an actual ASCII picture of the front of the radio, but it has the following controls sorta in the indicated positions:

```
+---------------------------+
+---+ TREB SET | |
|PWR| | |
+---+ BASS AM-FM | |
| |
BAL +---------------------------+
UpArow UpArow ==== ==== ==== ==== ====
VOL FADE TUNE
DnArow DnArow SEEK RCL SCAN
========= ======= =========
```

CONCLUSIONS SO FAR:
* It is obviously digitally-tuned and probably has only five digital memories for each band.
* The BALance control implies the radio has at least two speakers.
* The FADE control implies the radio has four speakers.
* Because the PoWeR switch BARELY depresses and does NOT have two distinct positions (instead, it has a plastic-covered hole probably for a pilot-light to show through), the switch probably controls some electronic circuit to turn the radio on and off.

GUESSING:
* Each group of three = = = pins probably belongs to one speaker,

and an internal examination may show the middle pin is ground.
* The HOLE in the top row EITHER
* doesn't have a connector hidden behind the plastic (in which
case the chassis will be GROUND) OR
* if there is a hidden connector, it will be GROUND (like a U-GROUND
outlet) (My reasoning: one would NOT want the matching connector
to have a hot 12-volt pin sticking out like a sore thumb!)
* The pin immediately below the hole will then be for +12 volts.
* Since all 13 pins are now "accounted" for, there probably is no
antenna-control power wire.

I am definitely open to other possibilities!

Thanks for the replies so far. They've been helpful, and have sent me on some interesting Google searches learning a lot about RDF in general. Some more specifics:

I have no preferred frequency ranges, but that is more out of ignorance than flexibility! In terms of transmitter power, in my first post I mentioned that a continuous signal wasn't necessary if that would help matters. It seemed plausable to me that a transmitter which used its power to transmit a short, strong signal could be detected at a much longer range than a weaker signal.

The reply regarding carrier phase was interesting, and sent me on a tour of GPS basics. Half the fun of this project is going to be learning new stuff. As I understand it, the reason you called this a "reverse GPS" is because the multiple receivers are in known locations instead of multiple transmitters. It would be feasible to build a second transmitter (a time reference?) and place it somewhere in the 100 yard square. There is a house roughly in the center of the property which would be where the "guts" of the processing equipment would be anyway. How does the carrier phase solution compare to VHF and shortwave in terms of power requirements, size of transmitter, etc?

Just to get a better sense of whether the range and resolutions I'm looking at are feasible, suppose you wanted to locate your local college radio station's transmitter. I just googled a few college stations and found two FM stations that transmit at 300 and 400 watts. The 300 watt station claims to cover 700 square miles. Of course I realize that: 1) "covering an area" may not be equivalent to "area within which their location can be pinpointed", and 2) Even if I could generate such power in a portable transmitter, I would need to choose bands so as not to run afoul of the FCC. (Just how much transmitting power can be generated from a garage door sized unit is another issue, and another reason the brief "burst" signal sounded preferable). Anyway, I was sidetracked there. To get back to the main question, if you had antennas at 4 corners of a 300 x 300 ft square lot, are there any good thumbnail estimates of how accurate you could be at locating the 300 watt college station, and how this accuracy varied as a function of the distance to the station?

In addition to being a fun way to learn new things and tinker with electronics, this project is also motivated by someone I care a great deal about who often works in isolated outdoor locations and doesn't own a cell phone or GPS. I know when she is at these sites, but worry she will be unable to call for help if something happens. Can she be located by her pushing a button and at what range?

She's already suggested building a Bat-Signal, but that is beyond by technical expertise. Also, she said that buying her a cell phone and GPS would be cheaper than building this monstrosity, but I like intellectual challenges and need to keep my mad scientist reputation well-exercised. :)

Thank you again, and please continue the excellent discussion.

Source record: 25929

Do you know of anyone using a transparent scale scale + lamp + lens + screen to PROJECT the tuning scale in a homemade device? This would be so retro cool!

I'd even be tempted to write in the names of a selection of broadcasters, coastal stations, nets, QPR windows, USN fax, GCSS, whatever....

I'd rather not mess with film and sprockets (a la Racal, was it?), while I would ask the local glass shop to cut me a glass pane disk to my liking, like a foot across.

As an added benefit, the disk itself would be rigid and stable enough to act as slow motion drive: I would turn it through a standard sized rubber covered shaft leaning against its rim, with some nice big knob on it.

For the scale proper, I'd start with a log scale using one of a number available free programs, print it on a transparency, and maybe add frequency marks (& icons, logos, etc.?) manually in a later version.

Hi foo bar,

I simply can't believe this works !!! But it really does!
I'm totally amazed!

It works so fine and you just became part of it, just like that,
without even knowing! Can you believe it?

You're at the same point I was last week. Just one more step and

YOU'LL RECEIVE A PAYCHECK as I have!

Listen to what happened:

Stephan Ducharme, the famous "FreeAdGuru" took up a challenge.

Stephan is doing this to prove that you don't need a website
to make money on the Internet !

foo bar I'm telling you, when this man gets mad, it rocks !

Stephan says:

"I have been surfing the web searching how to make money online
for over 3 years, day and night till 5A.M., with no results.

I wanted so much to succeed. I remember falling asleep on my
keyboard a few times.

I have seen so many web site owners working one entire month
for 10 to 100 bucks in net profits.
It is nonsense to work hours for nothing.
It has to stop !!!

I have made over a MILLION dollars in the past weeks.
And I have decided to reveal how it is done.

So Stephan has just created a RED HOT AUDIO EBOOK
Millionaire at 31...on the Internet

And ... foo bar You DO have Stephan's permission to give
it away to all your friends FOR FREE!

Yes, you heard me right!

You really can post the ebook to all your friends at no cost
to them and chances are YOU WILL EVEN RECEIVE A PAYCHECK
in your mailbox, just for doing that!!!

Imagine, getting paid by giving away something for FREE!

Do like I did:

Send it by email, through ICQ, MSN, in forums, newsgroups,
chat rooms, make ebook swaps.

I'm sure you know a lot of people interested in knowing
about a young 31 years old man revealing his secrets
on how he has just became a MILLIONAIRE from his PC at home.

Simply spread the news everywhere, it's OK!

And YES, The mind-boggling part is this:

YOU WILL GET PAID

Completely awesome!

I have made HUNDREDS OF DOLLARS in the very first few HOURS!!!

1. Click here to receive the letter to forward to your friends:

http://freeadguru.com/cgi-bin/i.pl?c=r&i=18549

2. This link will enroll you as an affiliate. It's very simple.
You simply need to enter your name and address telling
Stephan where to send your paychecks to.

It will take you 5 MINUTES max.

I JUST RECEIVED A PAYCHECK WHICH PAID THIS MONTH'S HOUSE MORTGAGE

My goal is to replace my job income because I don't want to be
kept in endless traffic jams anymore. I want to stay in my
warm bed on Monday mornings with Sabre and have the money
needed to have 5 days off a week instead of only 2!
Only 2 days off a week?! That's no fun.

More and more people are achieving this goal with the
Internet. Today, I'm standing in line and I'm the next one to
succeed. Come with me! Everybody's coming along this time
because it's actually working!

You're certainly asking yourself how this works? How can we
make money by giving away something for free?

The idea is prodigious...

Stephan is a genius mind!!

See, some of your friends will absolutely LOVE Stephan's Audio
ebook where he talks about how he just went from ground zero
to being a millionaire in weeks, thanks to the Internet.

After listening to Stephan's free audio ebook, your friends
will want to know more, so they will buy Stephan's famous
course "How To Get 1 Million Visitors On Your Website Without
Paying A Dime In Advertising - VERSION 2" available at:

http://moneyhome.com/cgi-bin/i.pl?c=a&i=18549

where he reveals ALL his secrets and shows us how he is
doing it STEP-BY-STEP.

The fun part is that by walking in the same footsteps
he's walking in, we're making it to the top too, as Stephan
is giving us up to 40% of the profits.

He is making OVER 1 MILLION dollars right now, and more than
$400,000.00 HAS BEEN SENT TO PEOPLE JUST LIKE YOU AND ME!

How can you start making money?

It's FREE.

Simply do these 3 little baby steps:

1. Register as an affiliate by going to:

http://freeadguru.com/cgi-bin/i.pl?c=r&i=18549

Where you will enter your name and your address.

2. You'll access your personalized area. Click on "Step-by-Step"
instructions to see the pre-written ads ready for you to
"Copy" and "paste".

(Or Look in the "Links" page. Link #1 will be the give-away free
access to the AUDIO ebook.

Or Look in the "Ads" page to select the pre-written ad you prefer
to send to your friends.)

3. Give that link to everybody you know. (Copy and paste)

A. Go into your email box and send it to everyone who has ever
sent you email. (Click on reply, paste your affiliate access
link to the free ebook. Click send.)

B. Go into your ICQ, MSN contact list and forward it to
everyone.

C. If you have friends in newsgroups, chat rooms and forums,
send them the audio ebook access too.

They will thank you.
Voil�. Finished. Wait for your paychecks.

Stephan will take care of everything from there and
you will receive a paycheck in your mailbox only for having
given away his RED HOT NEW Audio ebook for FREE!

Everyone who wants a second source of income will buy
Stephan's course.

Everyone who wants visitors on their website will buy
Stephan's course. (which is EVERY website owner on the
Internet... Tens of Millions of people NEED this course!)

And You get paid every time!

Think of the possibilities! The market is so wide right now
and the demand is so big that we are all making very good money.

To your quick success,

Hi!
I need help understanding a conventional phase/frequency detector.I consists of 6 two input NAND gates and 3 three input NAND gates.It compares the phase and generates UP and DOWN signals.I was wondering why the dead zone is high specially when there is a large reset delay path.

For the mating connector go to WAL*MART. In the auto section they have "conversion" plugs for GM cars/radios. Some of them have a wiring diagram included. If that doesnt do the trick look in a manual (at Autozone or pep boys) for a wiring diagram. The radios used in GM cars are pretty standard and interchangable...good luck.

> sorta thing.

I thought about the reverse-GPS approach, but couldn't figure out how to determine absolute position. The most I could come up with was that you'd know times-of-arrival at the various receivers, and that would give you deltas from the earliest time-of-arrival. But until you know the distance of the transmitter from any one of the receivers, you can't determine position w.r.t. _any_ of them. As soon as you have distance from one of the receivers and N deltas, you have a fix in (min(N-1,3)) dimensions -- assuming that the processor knows where all the receivers (or antennas, at least) is in that space.

So what am I missing?

OK, maybe reverse LORAN. If you know the difference in the times of arrival between two stations you can plot the hyperbolic surface where your transmitter must lie. With four stations you should have six different surfaces. The intersections won't agree, but you can get a maximum likelihood estimation of the transmitter's position in three-dimensional space.

Being a mathematician by trade would make this easier, and more fun...

Actually three receivers would do it unambiguously most of the time, but four would be more accurate at the cost of a bunch more math.

While I do computer science now, rather than math, my degree is the
5-year Bachelor's in math, for what _that's_ worth. Every now and
again I get to actually use a bit of real math at work, generally to
the amazement of the in-juh-nears here at WeBuildHighways.

My point here is definitely not to wave my degree, as I'm quite sure
that others here have degrees more advanced than mine, or do math for
a living instead of as a hobby, etc., but to point out that having
a math background didn't make it any easier for me. It's still fun,
though.

> Actually three receivers would do it unambiguously most of the time, but
> four would be more accurate at the cost of a bunch more math.

Seems to me that N+1 receivers gives you an unambiguous fix in
(min(N-1,3))-space: 2 receivers locate the transmitter on a line, 3
locate it on a plane, and 4 locate it in 3 dimensions. Since we only
get to sense 3 spatial dimensions, more than 4 receivers are useful
only to provide an overdetermined solution, which may permit more
precision.

Of course, the "closer" the receivers are to one another as seen by
the transmitter (think of the solid angle that the receiver array
subtends from the transmitter), the more ill-conditioned the matrix of
coefficients that one uses to determine the position.

An interesting variation on the problem would be one in which the receivers also received or derived some precise time signal, such as GPS time, and the transmitter to be located transmitted a signal which contained a precise time referenced to the same standard.

This turns out to provide a good location for the transmitter, I believe.

But if you put GPS into the transmitter for the time signal why not just have it get it's own position and transmit it, ala APRS locators?

(Shhhhhh! Pay no attention to the man behind the curtain.)

That, of course, is an elegant solution to the problem, but I didn't
consider it because it appeared to be outside the postulates given.

Since Delco is GM's electronics arm, why not try a
GM dealer? Or a car audio place?

You may have to trace the wiring, otherwise. There is
nothing wrong with doing so, nor is it in any way
idiotic.

If you want to build something that will locate the roving transmitter on your plot of land that is 300 foot by 300 foot it might not be too hard to do if you can get your four receivers to do a little bit of timing computations for you.

Set the roving unit up to send a pulse on a regular basis. It doesn't have to carry any data or anything like that and it wouldn't have to be too powerful either.

There are a few assumptions that can be made that are pretty definate.

1. The distance from two diagonal corners of the square is the maximum distance the transmitter can be from the receiver and still be in the area that is designated as home.

2. The transmitter should be home. If the calculations are coming out wrong then the transmitter has violated the bondary of home.

3. All four of the receivers must be set to a very accurate clock so that they are all using the same reference.

I don't have a calculator with me that will let me do the calculation to find the diagonal distance across the square so I will use 450 feet as the rough number for the maximum distance from any receiver.

The first receiver detects the transmit pulse and it is known that the transmitter is within 450 feet of that receiver. That starts a clock. The second receiver detects the transmit pulse and the time since the clock started is noted. The third receiver detects the transmit pulse and the time since the first receiver detected the signal is noted. With this much information the position of the transmitter can be determined on a two dimensional plot. The fourth receiver could be used for a sanity check to make certain that the transmitter is in the expected location and it would allow better coverage for when only three receivers can detect the signal.

The space between clock start and second receive detect is the difference in distance between these two receivers. The next detect is the difference in distance between the first receiver and the third. And lastly the fourth detect sets the distance between the fourth receiver and the first. If the math is done right there will be four circles drawn each has the center at the corner of your property. When the drawings are made they will all cross in only one place. There will be other places where two or three circles cross.

The nice thing about doing it this way is that there is nothing mechanical and with todays computing power that is available a solution can be had within milliseconds of the transmitter putting out a pulse.

An idea for the accurate clock could be to use a receiver at each receiver in the square to receive a local TV station and use the synch pulses as a reference. Just don't forget the propagation delay is from one side of the square to the other and figure that in.

Another option would be to put a GPS receiver at each corner and use the clock from these as your reference.

Or you could use a common receiver site and one clock feeds all four detectors. Just remember that there will need to be four receiver antennas and corresponding feed lines to take care of.

Delco was spun off some years ago and renamed Delphi. That might be the
place to look.

Just as Ford spun off its parts business as Visteon.

[Laura.. Didn't see you at Dayton this year.]

The "conventional phase-frequency detector" I know is the basic
circuit of the Motorola MC4044 package. That one is explained in
detail - in the form of a timing chart of ALL gate states with little
arrows indicating which gate acts on other gates - in the
September, 1982, issue of HAM RADIO Magazine in the "Digital
Techniques" column titled "Inside A Phase-Frequency Detector
(MC4044)." The particular timing diagram is rather straightforward
waveform diagrams rather than the symbolic logic-state graphics
others have used. I am the author of that column.

The "dead zone" you mention is due to differential gate delays
and can be minimized with high-speed logic families. It has
several causes depending on whether the signal input is leading
or lagging the reference input. The waveform diagram lets you
select either one and, with a schematic, see the path that causes
the differential gate delay.

This sort of thing was attempted in 1960-1961 by Ramo-Wooldridge
Corporation (the corporation that spun off what was to become TRW)
on HF direction finding using "time of arrival."

Essentially that project failed due to a need of absolute group-delay
control in the receivers, specifically in the IF chain.

While the same local oscillator could feed the mixers and be well
isolated from one another to prevent signal coupling around the

wrong path, the group-delay or relative phase shift of the various IF chains defeated the theoretical concept.

To stay within a 100m (or so) square, one has to work with the phases of the wavefronts so a superheterodyne type of receiver is not too swift unless each IF section is an absolute duplicate of the others. It might be possible with a DC (Direct Conversion) or "zero-IF" type, working with a specific audio tone (as an example), but that's more stuff for analysis.

Group delay in tuned amplifiers is not normally measured, nor was it a factor in the military R-391 receivers used for this project at R-W. My body was involved to the extent of others' wants to set up equal group delays but still others' wants had me on the short list for what is now termed "downsizing." [R-W eventually went kaput despite being the origin of STL and, eventually the space factory of TRW] As far as I know the project never made it to full promise.

Well, you wouldn't be using 12AU7's.

At the very least, you'd be using Compactrons to get maximum tube
count per envelope.

But likely, Nuvistors or sub-miniature tubes would be the only way
to do it, if it could be done, since they are so much smaller.

4010. What Tube to use???

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-28 07:36:08 UTC
From: Rick Frazier <rick@rickfrazier.com>
Message-ID: <40B6EC1F.DA2E620C@rickfrazier.com>
Source record: 25797

I'm thinking about building an HF linear, primarily for SSB use, and am having difficulty in choosing an appropriate tube (or tubes).

I want to be able to get full legal output (U.S.A.) with input of 55-65 watts max, so as to not tax an Icom 751a or 746Pro which would be driving. I'd prefer to be able to get to 160m, but could probably live with 20-10m if I had to. I want something that can "loaf along" without strain to prevent overtaxing components.

I may have access to a transformer that can provide 2100-2300 volts AC at several amperes, so I suppose I'm looking for a tube (or tubes) that can work with 2800 to 3300 VDC on the plate(s). (At the high end, it may be possible to provide 3200 volts and as much as 5 amperes of current... so at legal limits, the HV power supply should be able to keep up with little or no voltage sag.) Of course, something capable of high power output that can run along at way less than full output is preferred to another that has to run at the ragged edge to provide the same output. (It goes without saying that close monitoring is required to make sure the legal limits aren't exceeded, but that should be part of good operating practice anyway, IMHO.)

In your opinion, which commonly available tubes sound appropriate? I'm particularly interested in hearing from hams that have built units with similar DC supplies.

This is likely to be a long term project, with minimum amount of time to work on it at a time, and likely extensive amounts of time to find appropriate components at a reasonable cost (think beer budget and champagne dreams)..

Thanks
Rick AH7H

==========
If second hand tubes are not considered I suggest to have a look at the
Svetlana web site.
If valves can provide the wanted power at 29 MHz ,they certainly can do at
1.8 MHz.

If Eimac or similar tubes are available like the 3-500Z , 2 of those in
parallel are fine and so is a single 8877 or 3CX1500

Ref ARRL Handbook 1995 (and probably others) ,chapter 13

Good Luck with your project

But for this to work, as I pointed out in another post, you need to
know the true distance from the transmitter to any one or more of the
receivers already, or (equivalently) you need to know the exact time
of transmission relative to the receiver clock. Otherwise all you
have is the delta-Time Of Arrival (TOA) from the receiver that gets
the pulse first to the other receivers, and that's not sufficient to
locate the transmitter.

Even where the maximum distance is known, you still need the true
distance from the transmitter to any one receiver at a minimum. If
you don't have that, you can't draw any circles.

Or I'm missing something obvious. I really don't think I am, but if
someone can point out what I'm missing I _will_ be grateful.

Message-ID: <B_Htc.4677$pt3.1214@attbi_s03>
Source record: 25804

There are various fixes for the dead zone problem.
In the mid-1970's, Fairchild (the original company)
sold an "11C44" phase detector that got rid of the
dead zone by injecting a narrow pulse so that the
phase detector pulses would never have to try to
go to zero width. Eric Breeze holds the patent
on this technique; if interested read his patent.
Analog Devices makes that AD9901 phase detector
which gets around the dead zone by first dividing
the frequency by 2. However, it is not suitable
for a frequency synthesizer because of the large
spurious sidebands resulting from this technique.
Motorola had some patents on the circuits in its
MC145159 that dealt with the dead zone and sampling
sidebands. It also used a divide by 2 technique, that
was not documented; (we figured it out by observing
the chip's output). That chip may have been inherited by
On Semiconductor. It was originally developed for
some division of GE.

Hi,

Perhaps he has gas appliances ?

The dryer motor and timer is on 120 but heater element is 240
so his clothes would take longer to dry.

I agree with other post that he could have lost another part in the amp
or the main transformer has a short in the primary.

He could remove the transformer and bench test it using
small ac power supply to input 1-10 volts to the transformer primary
to test is in a safe way.

Source record: 25806

I currently have the following old radio-related books for sale. Postage (Media Mail within the US, at cost elsewhere) is $2.50 for the first book, and $1 for each additional item. The books are:

Worldwide Publications "White's Radio Log, Vol. I, Number I" Worldwide Publications, c1982. The 136 page softbound book is in good+ condition, clean with no page tears or pen marks. Not dated, but looks to be from the early 1980's. A directory of North American AM, FM, and TV stations including world-wide shortwave stations. Available for $3.

American Radio Relay League "The A.R.R.L. Antenna Book" American Radio Relay League, 1960. Nineth edition. The 320+ page softbound book is in good condition. The covers show some wear from previous use, there are a few bent page tips, and there is a previous owners address label inside the front cover. A good solid reading copy of this informative text on radio antenna technology. Available for $4.

Woodruff, H. Charles "Short-Wave Listener's Guide" Howard Sams & Co., Radio Shack, 1976. Sixth edition. The 136 page softbound book is in very good condition, clean with no page tearts or pen marks, and a strong binding. A collective list of worldwide shortwave radio stations listed alphabetically, by area, by frequency, and more. Available for $4.

Siegel, Hy "All About CB Two-Way Radio" Radio Shack, 1976, Soft Cover. The 112 page softbound book is in very good condition, clean with no page tears or pen marks. Nicely illustrated. Available for $3.

Frost, J..M. (Editor) "World Radio TV Handbook, The Authorative Directory of International Radio and Television (Volume 39, 1985)" Billboard Publications, 1985. The 600 page softbound book is in very good condition, clean with no page tears or pen marks except for a previous owners name and date at the top of the Table of Contents. Available for $3.

Federal Telephone and Radio Corporation "Reference Data for Radio Engineers, 2nd edition" Federal Telephone and Radio Corporation, 1946, Second edition. The 322+ page hardbound book is in about very good condition, clean with no page tears or pen marks except for a previous owners name stamp inside the covers. Green cloth covers. A nice early radio reference text. Available for $7.

Glasgow, R.S. "Principles of Radio Engineering" McGraw-Hill, 1936, First edition, eighth printing. The 520 page hardbound book is in very good condition, clean with no page tears or pen marks except for a previous owners name inside the front cover, and a few light pencil marks/notes in the text. Available for $8.

Nilson, Arthur R. and J.L. Hornung "Practical Radio Communication; Principles, Systems, Equipment, Operations" McGraw-Hill, 1943, Second edition. The 927 page

hardbound book is in very good condition, clean with no page tears or pen marks except for a preperty stamp inside the front and rear covers. A nice early radio text. Available for $8.

Everitt, William Littell "Communication Engineering" McGraw-Hill, 1937. The 727 page hardbound book is in about very good condition. Clean with no page tears or pen marks except for a previous owners name and address inside the front cover, and a few passages underlined in pencil. A nice early text on the science of the radio. Available for $8.

Institute of Radio Engineers "1933 Report of the Standards Committee of The Institute of Radio Engineers" Institute of Radio Engineers, 1933. The 225 page softbound book is in good+ condition, clean with no page tears or pen marks except for a previous owners name on the front cover. Some wear to the spine paper, but not too bad. Page tips in rear lower corner bent outwards somewhat. A neat look at standards development for the radio in the early 1930's. Available for $8.

Federal Telephone and Radio Corporation "Reference Data for Radio Engineers, 1st edition" Federal Telephone and Radio Corporation, 1943, First edition, second printing. The 200 page hardbound book is in good+ condition, clean with no page tears or pen marks except for a previous owners name inside the front cover. The pages are a bit wavey along the bottom edge, possibly from minor moisture exposure. Otherwise very nice. Green cloth covers over flexible boards. A nice early radio reference text. Available for $10.

Morecroft, John H. "Elements of Radio Communication" John Wiley & Sons, 1929. The 269 page hardbound book is in good+ condition. There is a previous owners name inside the front and rear covers, and light pencil marks/notes on many of the pages. Dust jacket has extensive tape reinforcement along the edges. A nice early text on the radio. Available for $10.

Smith, F. Langford "The Radiotron Designer's Handbook, 3rd Edition" The Wireless Press, 1941. The 352 page hardbound book is in about very good condition, clean with no page tears or pen marks except for a previous owners name and address inside the front cover. A nice vintage look at radio design. Available for $10.

Saveskie, Peter N. "Radio Propagation Handbook" New York, NY, U.S.A.: T A B Books, 1980, 1st Edition. Red boards. The 499 page hardbound book is in very good condition. There are address labels from the previous owner inside the front and rear covers, and an embossed property stamp on the title page, otherwise very nice. ISBN: 083069949X Available for $15.

Or, all of the above for $80 post paid (within the US). If interested in any of the above, please email to "Oldbooks78@aol.com" to reserve. Thanks.

Dave

Alas, the Svetlana site has expired -- Svetlana USA is not owned by the
company that owns the Svetlana factory, and they've had a falling out.
The Svetlana factory in Russia now markets their tubes as "circle C"
(the Tubes Formerly Known As Svetlana?), but all the nifty articles
aren't accessible.

The ARRL makes sure to include a few linear projects in each handbook,
so there's plenty of choices. I'd make concrete suggestions, but 5
watts is QRO for me.

If you know the positions of any two receivers, and the time delta between the reception of the pulses from the transmitters, the set of possible positions of the transmitter lies on a hyperbola that intersects the line between the two receivers.

With two pairs of receivers you get two hyperbolas and two intersections -- and three receivers gives you three pairings to calculate with.

So you don't need to know the absolute time of the transmitted pulse, just the difference.

Depends on how much bragging you plan on doing about your amp. Some folks wouldn't be caught dead with anything less than a pair of 8877's, just to keep ahead of their peers. "I tell you what ... I can run full legal limit with only 1/2 watt drive". Personally, I have run a pair of 3-500's for years without any undo strain on the components. Look at the photo's of the "big gun" DX multi-ops ... W3LPL, K0RF, and the like, many run some beat up, homebrew, single band amp running a pair of 3-500z's, to 6/6/6 at 200 ft. So you see where their money goes.

Plus, have you looked at the cost of tubes lately?

Check out the contesting.com (I beleive) archives of the [AMPS] email list. That should provide hours of reading towards your project.

GOOD LUCK!

How cool. There has to be some kind of saga behind this whole Svetlana business.

The "dead zone problem" is less a problem and more a
state of mind. :-)

When implemented with a charge-pump circuit (voltage
& time converter to current) between the PFD and loop
filter, it rather disappears into the woodwork of the whole
PLL. The phase difference between signal and reference
is proportional to the control voltage of the VCO producing
the basic frequency. There is ALWAYS going to be a
signal versus reference phase offset when the entire loop is
in lock so this dreaded "dead zone problem" will only show
up in a very narrow range of controlled frequency.

General intuitive thought on any PLL or other synthesizer
closed loop is that the relative phase between signal and
reference is zero. It isn't. If it was, then the VCO could not
be controlled. As a very rough indicator of VCO frequency,
that signal v. reference offset phase exists for quick scope
checking...when the control voltage range of the VCO is
known. Good for a quick bench check.

In practical terms, that dreaded "dead zone" isn't visible in a
real-world example.

Case in point: 23+ years ago, Rocketdyne Division of
Rockwell International (now a Division of Boeing) was beginning
work on a Deformable Mirror for laser work (they had a sizeable
optics group) that used a 1 MHz signal out of optics to indicate
the light phase error of an optical interferometer. I rigged up a
74H family phase-frequency detector circuit as the heart of that,
an integrator out of that into an A-to-D converter to get a digital
version for computer data manipulation. By all the careful
measurement, the expected dead zone didn't show up on any
graphing and the standard lab time interval counters could
resolve, accurately, 2 nanoseconds using time averaging.
[translates to rather less than a degree of phase error] The
optical physicists had been hopping up and down about "dead
zone" in meetings but the actual circuit performance didn't show it.

One reason for the non-observation of any dead zone is that the
digital gates forming the PFD were so lightly loaded in other-gate
capacitance that their propagation delays all tended to be the
same. Datasheet values of propagation delay of gates are all given
as maximums, rather worst-case things with lots of pFds connected
to outputs, etc. Put on half a prototype board, loaded only by other
gates of the PFD and the resistor input of an op-amp integrator, the
capacitance loading was minimal. [project was successful, and
spawned more work on deformable mirrors]

It can be an interesting academic problem to achieve a zero dead-
dead zone effect in a PFD, but thats about it. When working at
the comparison frequency of less than a few MHz, the PFD dead
zone due to differential propagation delays of the gates disappears
into the woodwork when using 74LS or faster digital families.

There's plenty to be concerned about in any frequency synthesizer
subsystem, but a phase-frequency detector gate structure is a
very minor problem in my opinion.

DDS and fractional-N loops in synthesizers have their own problems
such as spurious output, but those problems can't really be traced
to any PFD dead-zone effect. A PFD is wonderful as a control loop
element in that it can control a VCO (of the loop) from way off the
frequency and bring it into a lock phase range...from either worst-
case start-up frequency. [way back in the beginning of radio time,
lock loops had to use sawtooth sweep circuits to cure that start-up
condition, and couldn't control beyond +/- 90 degrees of phase
shift...PFDs easily handle +/-180 degrees]

You'll save time and money by getting a used Heathkit SB-220 for about
$500.00 or less and add 160 to it, or a Drake L-7 about $700.00 or more..
Both use two 3-500Z and are well engineered linears. And after you're tired
of it you can get most of your money back. Even if you put time in effort
in you'll get very little back. So get a 220 or L-7 and start collecting
parts for your dream when you find them cheap. JMHO

Len - Avery, whomever,
Our experiences differ. When designing PLL synths back then for two-war radio, we always saw the dead zone. In a type 2 loop (hope I'm remembering my control theory correctly) the extra integration allows the VCO to float around within the dead zone, causing a low freq rumble at times. You could watch the phase wandering around on a scope on the two PD inputs. We would force some small leakage current just to hold it up against one side of the dead zone. Perhaps the types of requirements causes the difference. We were in the audio range with the PD reference freq and lock times in the tens of ms. if I recall correctly.
If I recall, the Fairchild chip did a better job of matching the delays. The small overlap causing a narrow pulse to occur seemed like a small issue - not much energy at the ref freq for some applications. Our synthesizers were of such requirements that there was a very tight balance between lock time and spurious. The loop filtering took much care to get the lock time and keep reference spurs down.
I designed and built what I still believe is the first 2-meter synth hand held in 1973. 8.0 ma current max drain (varied 'tween 6.5 and 8 across the band), 70dB spurious (the radio originally was 43 dB). 5kc resolution. In a Motorola HT-220. Still have it. A year later I got tired of doing the dip-switches and designed a keyboard entry system. That fella with the HT-220 site didn't put it on. He does have Dale Heatherington's (sp) though (got a couple of them also).

Dead-zone = phase noise. Very little dead-zone = very little phase noise.
Bigger dead-zone = bigger phase noise.
You can interpolate the rest for yourself.

Joe

Withoug the previous parts of the thread this may be duplication since I
don't know the original constraints...but

I have always wanted to build a model rocket altitude transponder using this
concept:

On-board the rocket we have a "transponder"... a one transistor superregen
Rx on, say 10 or 6 Meters. I hae a schematic around here somewhere for a
one tranny FM broadcast receiver from Pop Tronics. Have it's demodulated
signal modulate a 2 meter TX. This can be a 9 or 12 Mhz. xtal osc and 2
meter tuned circuit (gets you a few miles on the ground from a tower
receiver).
On the ground you have the "Ground Station" 10 or 6 meter mobile. Since
you can have lots of power, the crummy Rx onboard the rocket is no problem.
From the mobile, transmit a tone. Measure the time delay of a zero crossing
of the transponded tone. A simple freq counter can be made to do this if it
had (I forget the official name--triggered event counter maybe??) the
ability to start counting on the TX tone's edge and stop on the RX tone's
edge. Just a few chips for this.
You pick the frequency that the counter is counting to display feet or
whatever units you like.
What's-it, something like a nano second per foot?
You also need a delay in the proper place to account for the "zero distance"
delay of the receivers & transmitters.
Seems like one other "Ground" receiver is all that's needed to triangulate
the location horizontally...

There was an article in QST within the last year or so where some fellas
measured the delay through a, I think, 2M repeater versus distance...same
concept, 'cept they just used a dual trace scope..

==========
A few years ago I bought 3 pcs at a flea market (connection diagramme
showing external components included)
The diagramme shows . Supply voltage 12 -15 Input 200 mW @ 50 Ohms
Output 20 W @ 50 Ohms.
Would also be very interested in spec sheet.
Question : Has this module linear characteristics ,hence can it be used for
SSB or is it just for AM & FM ?

Has anybody here attempted to use a pic to control a dds chip (and wrote the software himself)? I was looking at G3XJP's article on his 'pic-n-mix' vfo using an 16C84 to control an AD9850. I can't belive he was able to get all that functionality into just 1k of code and 64 bytes of eeprom. (you can find his article as an apnote on the Analog Devices web site ... AN-557 is the number)

I'm thinking of using the AD9954 dds chip instead of the 9850.

I'm just starting to look at what's required in code to get from a BCD input to the DDS word. Keep in mind G3XJP didn't hard code his clock as a constant, it can be adjusted. The formula to get the DDS word involves some math with fractional parts, it can be done in interger math with some scaling or lookup tables, but there isn't much room in a pic. I just ordered some 16F88's with 4k of program space and 256 bytes of eeprom so I would have a little more room.

Any starting ideas would be welcome!

It's really not difficult at all once you understand the DDS serial message structure. I did it in PICBasic with a 14F675 and a AD9850 DDS for my HF Lab System, including a 9600 baud software UART and a few routines that do analog capture and log detector calibration (http://mysite.verizon.net/jdrocci/). The whole code footprint was about 600 words if I recall, and it could be much smaller if it were coded in assembly, as the Basic compiler loads a number of subroutines that don't always get called. If you're daunted by the math involved, PICBasic might be the way to go as it includes multiply & divide capabilities.

I'm not familiar with the picbasic, unless thats an extension of the
basic stamp product. I'm fairly good with assembler code, though the
pic processor is new to me (I'm more familiar with the 8051, 80x86
and other Intel processors). The pic seems to be a much simpler
instruction set (more RISC like). Compared to the 8051, the
instructions per clock on the pic look a little better than the
8051 so performance should be good.

The work that needs to be done seems clear to me, the best way to
write the needed basic routines in assembler (for the pic anyway)
will take some study, to get the fewest lines of code required to
fit in the limited space. If anybody has good binary to bcd and
32 bit multiply and divide routines alread written it would help
not to have to re-invent those wheels. (Maybe a search on google
is in order here).

My pet-pieve on ham projects published in magazines are those
authors that DONT make their source code available, but sell
burned proms or pics. Publishing a construction article using
a micro without the source code available is like NOT providing
the schematic, but offering a PCB!!! How are hams going to
improve the state of the art if we don't share!!!

Ok off the soap box!

>Dead-zone = phase noise. Very little dead-zone = very little phase noise.
>Bigger dead-zone = bigger phase noise.
>You can interpolate the rest for yourself.

I have to disagree with some of that.

First of all, a "dead zone" or the almost-exactly-in-phase condition,
occurs at only one VCO frequency where the control voltage sets
up the frequency for that in-phase condition.

Yes, at that exact frequency, there COULD be some phase noise.
But, the phase noise may NOT be from this "dead zone" effect.
Phase noise can come from MANY different sources. If it occurs
well away from the in-same-phase "dead zone" then the phase
noise is NOT caused by any "dead zone."

The relative phase between signal and reference inputs to a PFD
correspond to the VCO control voltage (times the charge-pump or
integrator circuit constants). Signal and reference phases when
in lock will always be offset from one another, one leading and one
lagging. A good loop will show a constant offset of phases even
when both inputs hold a constant phase.

"Two-war radio?" PRC-25? Term not understood. Experience has
hands-on with everything from a PRC-8 to a PRC-104, but little with
the PRC-25 or -77.

>In a type 2 loop (hope I'm remembering
>my control theory correctly) the extra integration allows the VCO to float
>around within the dead zone, causing a low freq rumble at times. You could
>watch the phase wandering around on a scope on the two PD inputs.

If the loop is set for something like a 10 to 50 mSec lock-in time,
one has to look quick to see the actual lock-in. If the loop is
designed properly (VCO control voltage gain, time relative to the
reference frequency), there should not be any "wander."

In order to see the settling time from a large step-function of
frequency change, you need to sync a scope from the step
source and watch the jump-and-settle of the control voltage like
a damped sinewave. That's a quick check of loop control
action. Storage scope (old way) or digital scope (muy better)
are the best way to view that.

>We would
>force some small leakage current just to hold it up against one side of the
>dead zone. Perhaps the types of requirements causes the difference. We
>were in the audio range with the PD reference freq and lock times in the
>tens of ms. if I recall correctly.

Most of the older PLLs had reference frequencies of 1 to 5 KHz.
That's a period of 1.0 mS to 200 uS. Without about 5 to 10
cycles for settling-in (to near invisibility), that would be about
10 to 2 mS, rather quick.

> If I recall, the Fairchild chip did a better job of matching the delays.
>The small overlap causing a narrow pulse to occur seemed like a small
>issue - not much energy at the ref freq for some applications. Our
>synthesizers were of such requirements that there was a very tight balance
>between lock time and spurious. The loop filtering took much care to get
>the lock time and keep reference spurs down.

Regardless of the loop filter type, those are always fussy to avoid
pickup contamination of the VCO control line. But, knowing the
control voltage characteristics (delta-V v. frequency) over a range,
the design is strictly textbook formula stuff. It helps greatly if the

VCO control characteristics are linear versus frequency AND the division ratio maximum to minimum number is as small as possible.

I've seen a few applications where both the control voltage characteristics were very non-linear AND the division ratio of the PLL greater than 2:1 with the end result being an almost impossible lock at the extreme ends of the tuning range. One case was alleviated by extra circuitry from the division control to generate a DC bias summed with the control voltage. Not too swift since it took more parts, but better than failure.

In my own case, the filtering and shielding around the PFD to VCO had to be rather severe in order to keep it stable (too much high-energy circuitry rather nearby). Once that was achieved, there was no wandering at a 1 KHz reference input with proper values of known control voltage constants and accurate calculation of loop filter values. It was "tight."

I'm still following this thread with interest and looking up things that I don't understand. The recent exchanges of the past day have gone quite over my head, but I'm reaching.

In my travels, I found this link. It seems this setup is using two antennas, but I'm wondering if a similar 4-antenna solution could be used for what I am trying to do. It would seem that the ability to use a common PC audio card and readily available software would be a big bonus. Comments welcome, particularly if this idea is way-off what I'd need! The URL:

Let me try again to explain dead zone.

Many PLL's never experience the dead zone because the loop
filter is constructed using op amps with high (10 mV)
offset voltage specs. This offset forces the loop to
lock up outside the dead zone. If you use a low offset op amp,
and then put in an offset adjust pot to take out any
residual offset from the phase detector, you can observe
the spurious sidebands at the phase detection frequency
null out. However, you will then find that the loop bandwidth
has changed substantially, because you are in the dead zone
region. The VCO will get more phase noise because the
loop wanders around (like a bang-bang loop) in the dead
zone, and/or the change in loop bandwidth has de-optimized
the suppression of VCO noise by the PLL. I have
personally observed this and other engineers I have
mentored have also observed it (after first arguing with
me that it wouldn't happen). By the way, the pot
tweaking to null sidebands doesn't hold over temperature
(no surprise) so it's still bogus even without the dead zone
issue.

To correct previous misinformation about the 11C44: the
gates are not better matched; rather there is an extra pulse
injection circuit as described in Eric Breeze's patent. This
information is from a conversion with Eric Breeze 28 years
ago. The 11C44 hasn't been available for many years but
that was due to mismanagement of Fairchild (which
was bought by National) rather than lack of merit of
the 11C44. (There was a lot of great technology at
Fairchild screwed up by mismanagement).

If you build a PLL with a low offset op amp (not the usual
ones with 10 mV offset spec) and then use a pot to tweak
out the residual phase detector output offset voltage, you
will see the sidebands on the VCO null out at a certain setting
of the pot. At this setting, you will typically be in or near
the dead zone. Although the spurious sidebands are impressively
low, the loop bandwidth will now be unpredictable, which
may de-optimize the phase noise. Also, there may be a lot
of low frequency residual FM on the VCO because the loop
is acting like a bang bang loop. Many engineers have never
seen this happen, because it is unlikely to happen by accident.
BTW, the pot setting won't hold very well over temperature.

I have observed this phenomenon as well but it seems
to be mainly an issue with beads or shapes with small
holes. The bead magnetizes from the inside out.
Larger "toroids" with sizeable center holes don't magnetize
as easily. This make sense physics-wise since Ampere's
law says H is inversely proportional to radius.

Ken,
PICBasic isn't a "Basic Stamp". It's a true compiler that you program in Basic and it produces PIC object code that can be programmed into any PIC. There are also several "C" compilers that have similar capabilities. I like PICBasic because it takes care of all the initialization housekeeping, has a watchdog timer, and contains many useful high-level directives for things like software A-D conversion, software UART, SPI serial I/O, math, & much more. The best product is made by made by Micro Engineering Labs (www.melabs.com) and they call it PICBasic Pro, but their product is a little pricey. There's also a $20 version from www.oshonsoft.com that's essentially the same. Both compilers make PIC programming a breeze, and also produce relatively tight & fast code. Also, you can mix Basic & assembler in your source program if you wish.

Wander on over to
http://www.amqrp.org/elmer160/board/index.html
and click the 'Test Software.ZIP' link. In the source is just a few lines
to control the DDS. That particular program does everything but the kitchen
sink, and the DDS part is just a tiny fraction. The advantage here is that
the DDS code is split out, and you can see just how simple it really is.

Then, click on the 'VFO Software.ZIP' link. That piece of code for the same
hardware is really focused on the VFO capability, and has all sorts of
features.

I think Craig still has the original code still in there from WB2V that
allows you to calibrate your oscillator against WWV. If not, the original
'SigGen' code does. Google for SigGen, WB2V, WB9KZY or AA0ZZ.

In article <bWTtc.11435$eY2.451@attbi_s02>, "Rick Karlquist N6RK"
<richard@karlquist.removethis.com> writes:

>Let me try again to explain dead zone.
>
>Many PLL's never experience the dead zone because the loop
>filter is constructed using op amps with high (10 mV)
>offset voltage specs. This offset forces the loop to
>lock up outside the dead zone.

With any phase-frequency detector, the width of the output
rectangular wave (from the digital portion) is proportional
to the control voltage output. That width can be converted
to a DC control voltage by a charge pump (pins 4, 5, 10, 11
in either the MC4044 or 11C44 package) or done externally
in an integrator such as with an op-amp.

When locked, the signal and reference inputs of the PFD will
be in-phase but the relative phases are offset in time. It is
that offset which eventually produces the control voltage that
brings the VCO into the in-phase condition.

A "dead zone" does indeed exist in all such circuits but it
will take effect ONLY in the VCO frequency region where the
phases of signal and reference input are the same or very
nearly the same. At any other VCO frequency the "dead zone"
has no effect since the phase offsets of signal and reference
are away from that "dead zone." Note: The signal and reference
phases will be "in-phase" meaning that they are both on the
same frequency but the signal is offset in phase from the
reference.

The "offset" of any extra circuit elements to an op-amp used
in coupling the PFD to the VCO can be used as a stop-gap
cure for the "dead-zone" but that still is effective only in the
phase relationship of the signal v. reference inputs where they
are nearly the same phase.

>If you use a low offset op amp,
>and then put in an offset adjust pot to take out any
>residual offset from the phase detector, you can observe
>the spurious sidebands at the phase detection frequency
>null out.

Observation shows the entirety of the loop action. It does
not pin down a cause of the spurious outputs. Those spurious

outputs can be caused by a number of different things.

>However, you will then find that the loop bandwidth
>has changed substantially, because you are in the dead zone
>region. The VCO will get more phase noise because the
>loop wanders around (like a bang-bang loop) in the dead
>zone, and/or the change in loop bandwidth has de-optimized
>the suppression of VCO noise by the PLL.

The VCO control voltage curve sets part of the loop filter's
frequency response and is called the "gain" of the loop
feedback. Bandwidth is dependent primarily by the
reference frequency plus the lock-in response time desired.
Too much "gain" and the whole loop goes into oscillation,
never settling down; too little and the loop takes a very long
time to lock in (and may never do so). Curvature of the slope
of the PFD output (converted from time to voltage) affects the
"gain" and thus the total closed-loop condition.

>I have
>personally observed this and other engineers I have
>mentored have also observed it (after first arguing with
>me that it wouldn't happen).

The "dead zone" does indeed exist but I'm simply saying that
(1). It isn't an ogre ready to strike fear in use; (2). It doesn't
effect a PLL lock over all VCO frequencies...just that narrow
range of VCO frequencies where the relative phase offsets of
the signal and reference inputs to the PFD are about the same.

The original question involved a six 2-input, two 3-input, and
(one 4-input) gate EQUIVALENT of the '44. That original '44
design is an elegant one, a sort of gigantic flip-flop on steroids
which will work over a +/-180 degree range. It is far superior to
the old types of phase detectors which had only a +/- 90 degree
operating range. The time characteristics (or phase relationship
of input rectangular signals) of such a circuit can be much
improved by using faster-responding digital logic families. By
using 74F or 74H or other very fast gates, the "dead zone" can
be made very small, enough to essentially forget about any such
effects on the overall PLL with a 10 KHz or lower reference
frequency.

If there is anxiety over the PFD operation, it can be examined
with a 'scope and a stable, delayed signal pulse synced from
the reference input. The '44 circuit type doesn't need square
waves but can operate solely on leading edges. With a time-
interval-averaging counter, the signal input phase can be set/
characterized very accurately as well as the output pulse width.
Lacking a time counter, a 'scope (hopefully with delayed time
base function) can be used for coarser measurement. The
'scope will display the "dead zone" condition.

>To correct previous misinformation about the 11C44: the
>gates are not better matched; rather there is an extra pulse
>injection circuit as described in Eric Breeze's patent.

That's not included in the diagram shown on the 11C44 data sheet website you referenced. That gate diagram and charge pump and Darlington bipolar circuits are exactly as in the original Motorola '44 data sheet. Either PFD gate arrangement can be duplicated using "discrete" logic gates.

In my opinion there's an elegant simplicity of the '44 gate arrangement which adequately fulfills its purpose of not only operating over a +/- 180 degree input phase offset but also staying on extremes of low or high frequency signal input condition, ideal for PLL start-up. I'd like to know the original circuit designer to send thanks for such elegance in circuitry.

Other manufacturers (such as RCA and Intersil) have duplicated the '44 PFD gate arrangement with success. It can be copied with ordinary logic gates without problem. If there is a region of a PLL to concentrate on, I'd say it is in the pulse width to DC control voltage following circuit and the loop filter (and its shielding and isolation).

Hi everybody,
I would like to build a regenerative shortwave tube receiver using the
1U4 and 3A5 battery tubes. I know this is a very vague description of
the project. At one point I had a schematic that was sent to me by an
OM in VE land but I misplaced (lost) it. If anybody has something
along this line please let me know.
Thanks

Message-ID: <Tz5uc.14050$eY2.3710@attbi_s02>
Source record: 25841

My Metcal RFG-30 soldering system power supply quit on me a week or so ago, so yesterday I decided to look into
the problem. After removing 8 screws holding two bottom covers I was able to slide out the front and back dress panels for very limited access to fasteners. I couldn't find any way to unfasten the top cover which would allow separating the two halves of the case, but that turned out to be unnecessary. The single power transistor, an IRF130 TO-3 case FET was mounted with nuts on studs that came up through the mounting holes. One end had a Nylon shoulder washer under the nut but the other end made electrical contact with the case and was found to be barely finger tight. Since that had to be the drain connection to the device, I gently firmed up that fastener and reattached the cables to test the unit - - back in operation. I was particularly impressed with the toroidal power transformer in the base - - that had to cost the manufacturer some serious cash. If anyone knows how to remove the plastic top panel, that knowledge will help improve the serviceability of this excellent product.

I've never been able to find any historical reference to the MC4044
designer. It seems to be one of those lost pieces of history.

It's Jim Thompson, over in sci.electronics.design

He did some other famous ICs, like the MC1488 and MC1489 RS-232
pair, and I believe he did the MC1468 ECL VCO.

If you buy the RCA Receiving tube manual (RC-19, I think it's the 1959 version) from Antique Electronic Supply it has a schematic for one using two 1U4's and a 3V4. You need the book anyway...

There is a discussion on sci.electronics.design on this same subject (spawned by Deepthi as well). Turns out that one of the regulars over there, Jim Thompson, is 1/2 of the designer of this part, and the 12xxx series replacement for it.

If you go to Antique Electronic Supply you will find some books by
Lindsay on this. Lindsay also has his own web site. Their are some
kits on the Anitque site too.

>> > SNIP >

See also 'The PLL Dead Zone and How to Avoid it', A. Hill & J. Surber, RF Design, March 1992, pp131-134. The authors were with Analog Devices and compared the performance of the AD9901 with that of the MC4044.

My understanding of the AD9901 is that it behaves as a edge controlled frequency detector, until it gets close enough in frequency, when it switches to being an EXOR phase detector.

I am struggling to understand the comment above that the AD9901 is not suitable for use in frequency synthesisers because of the large spurious sidebands arising from its use. What causes the additional sidebands ?

Elsewhere in this thread there seems to have been some debate on the operation of the phase frequency detector. IMHO if the phase detector has a tri-state output then the loop over time must lock with no phase difference between the reference and controlled signals, ie 0 degrees.

I know, with the PS2A series, you have to remove the plastic overlay on the top panel to remove it, but I am not sure about the newer units. Actually, it is a pretty cool design, using a PWM scheme to control the power output. I've got a couple of the units.....I keep one at work (the small 400kHz unit) and the other one at home (the 13.58MHz unit).
These units do have short circuit and open circuit protection.

Right. Aluminum has better conductivity per gram than copper. I
understood that even before you original post.

I also know that aluminum also has much _worse_ conductivity per unit
volume. And that the core that you're going to put it on can probably
accept a finite volume of wire. Since 12 gauge wire has about 50% more
area that means that you're only going to be able to put on 2/3 as many
turns, meaning your inductance is going to be about half of what you'd
get with copper wire. Even with a toroidal core you're still left with
about 2/3 your inductance.

That means that you need to go to a bigger core to get your inductance up. Not only does this mean that you'll be adding a lot of mass, but a bigger core will require more wire, so when you're done you won't be getting a 2x savings in wire mass, and you'll more than likely have an inductor that is actually heavier than the copper alternative.

So, to repeat, have you run _all_ the numbers and verified that you'll achieve a savings?

--

Tim Wescott
Wescott Design Services
http://www.wescottdesign.com

Perhaps use silver-plated copper in the inductor and aluminium in the busbars. Nothing to say that you have to use only the one material throughout.

I've got a couple of the later PS2V units. They have four screws securing the top cover. Just out of curiosity I removed it on one of the units and the Al panel beneath it carrying the On/Off switch and the LEDs. Everything inside seems fairly accessible for servicing, including the output device - a VN0106, I think, in a TO220 package.

Perhaps I could put one of them on 14 MHz by changing the crystal. 8-)

operation
> of the phase frequency detector. IMHO if the phase detector has a
tri-state
> output then the loop over time must lock with no phase difference between
the
> reference and controlled signals, ie 0 degrees.

Theoretically, the edge controlled PFD locks the signal & reference with 0 degrees phase error. When the loop is locked, the output pulses from the PFD are theoretically infinitesimally small. However, neither the PFD chip nor the external charge pump/loop filter are perfect. Any leakage in the charge pump and/or loop filter causes the PFD to continually output wider than normal pulses in order to supply the additional charge current necessary to make up for the current leakage. This results in a non-zero phase error at the PFD inputs.

> I am struggling to understand the comment above that the AD9901 is not
suitable
> for use in frequency synthesizers because of the large spurious sidebands
> arising from its use. What causes the additional sidebands ?

As mentioned, the PFD output pulses approach zero width at lock, making it easier to filter the pulses down to pure DC in the charge pump/loop filter. The XOR PD will output a 50% duty cycle pulse train at lock. This is much more difficult to filter down to pure DC, resulting in modulation of the VCO, and thus sidebands.

This thread seems to be cloned from last week ; anyway as I said then silver mica are known to be subject to scintillation which may be due to de-lamination , later mica used powdered mica which may or maynot be better. Encapsulated low value caps are often degraded by the encapsulation material so sm would be better use NPO ceramic, microwave types should be lower loss.
Crystals jump in a changing temperature due to unwanted modes passing through the main mode as they have different temperature coeggicient. These are fairly gross effects of .01 to 10ppm jumps.

Not quite it. In order to derive a control voltage for the controlled
oscillator, the PFD output MUST BE A FINITE WIDTH.

In lock, at any frequency increment, the relative phase of the signal
and reference is constant, stable, BUT THERE IS ALWAYS A
PHASE OFFSET. This is necessary in order to derive the control
voltage which keeps the VCO in lock.

It's a common misconception to think of phase lock or even
phase control as trying to achieve a "zero degree" condition with
no phase offset. What is achieved in phase lock is a STABLE,
BUT OFFSET, phase relationship between signal and reference
frequencies at PFD inputs.

The easiest way to prove the condition is to scope an adjustable-
frequency PLL at the signal and reference PFD inputs and then
the '44-type PFD output into the loop filter. [measure the VCO
frequency separately if desired to prove the VCO, if desired] At
one locked frequency of the VCO the PFD output is a finite-width
pulse at the reference frequency. Change the divider setting for a
new VCO frequency and the PFD output has a different pulse
width. That can be confirmed by the DC control voltage...one value
at the first frequency setting, another value at the second frequency
setting. That DC control voltage is, in effect, an average value of

the pulse width out of the PFD.

>easier to filter the pulses down to pure DC in the charge pump/loop filter.

No. In the '44-type PFD, the output pulses will be zero ONLY if
the divided VCO is way off frequency, at one end of the controllable
range or the other. IN LOCK the PFD output will ALWAYS HAVE
A FINITE PULSE WIDTH at the reference frequency repetition rate.
Without that pulse width averaged out there would be NO control
voltage to hold the divided VCO within range.

>The XOR PD will output a 50% duty cycle pulse train at lock. This is much
>more difficult to filter down to pure DC, resulting in modulation of the
>VCO, and thus sidebands.

It is no different. Control voltage averaged out of an XOR phase
detector is still from essentially the same finite pulse width. [those
have worked for years without any comments about "spurs"]

The vast difference between an XOR PD and the '44-type PFD is
that the XOR PD is limited to a +/- 90 degree control and can't
tell the loop how to come off of a start-up condition which is way
off to one side of the VCO range or the other. The '44-type PFD
works over +/- 180 degree range and DOES indicate a way-off
VCO signal frequency condition. It will start up safely. In the
old PDs limited to 90 degree range, the general way of starting
up was with a very slow sawtooth generator algebraically adding
to the control voltage...once the lock range was achieved, more
circuitry shut off the sawtooth. [lots of extra parts]

In either type of phase detector, the amount of reference frequency
ripple out of the loop filter is dependent on the type of filter and the
speed of lock-in time on changing frequency of the VCO through
the divider setting. On can make the loop filter very slow and cut
the (awful, terrible) spurious sidebands down...and also waste
literal minutes waiting for the PLL to lock in.

Those (awful, terrible) spurs at increments of the reference
frequency are seldom worth worrying about in a PLL with good
shielding and decoupling around the control voltage parts of the
PLL. [the proof lies in tens of thousands of simple PLLs working
all around the globe without worries over "not working" because
their spurious outputs are "too high"]

In the digital PFD, there are essentially two outputs that drive the charge storage circuit; "pump up" and "pump down". If there is a phase error, the corresponding output produces pulses that are exactly proportional to the time-error between the two PD inputs. If the time error corresponds to a leading phase relationship between VCO and reference, then the "pump down" output produces pulses equal in width to the lead time, discharging the charge storage element. If there is a lagging relationship, then the "pump up" output produces produces pulses equal in width to the lag time, charging the charge storage element. If there is no error , then neither pump output produces any pulses, and the charge storage element just 'holds' the last charge it had on it. In a practical PFD implementation, it is impossible to maintain the zero pulse-width point because the PFD is a digital feedback circuit, and you would need parts with zero propagation delay to make such a circuit. However, the width of the pulses in modern designs can get down into the nanosecond range at lock. For this reason, the PFD can produce much lower sideband content than the XOR, which outputs large pulses at lock. The larger the output pulse, the more difficult the loop filter design.

> No. In the '44-type PFD, the output pulses will be zero ONLY if

Wrong again! With large frequency errors, the PFD produces constant pumping. If it didn't, it couldn't acquire with phase errors larger than 180deg.

You are also wrong in asserting that the lock-in range of the PFD is +/- 180 degrees. In fact, it is infinite (in theory). Yes, its linear output compliance range is +/- 180 degrees, but it can acquire lock even when there is an infinite frequency error. This is because once the PFD output exceeds it's compliance range, it outputs a constant "pump up" or "pump down" pulse train, which in turn causes the loop filter voltage to ramp up or down as the case might be until the signal comes back into the compliance range and lock is established. In practice the range is not infinite, only because you can't build a VCO with infinite tuning range or a PFD with infinite clocking

speed.

The XOR's big advantage is that it is simple, and there is no discontinuity around the phase lock point (as there is in the PFD), but it does not lock up readily in the face of frequency errors. The PFD's advantage is that it readily locks up, even in the face of large frequency errors and it also produces an easily filtered output.

4082. An easy to build SSB transceiver

Newsgroup: rec.radio.amateur.homebrew
Date: 2004-05-30 21:04:14 UTC
From: farhan@phonestack.com
Message-ID: <fcc11bcf.0405301304.7d022e71@posting.google.com>
Source record: 25719

I have just completed a new SSB transceiver that is very easy to build
and fun to use.
It is specially designed for beginners.
Check it out at http://farhan.net.co.nr/bitx.html .

Highlights are:
1. Very few coils to be wound.
2. Just 16 common 2N222 varity transistors used everywhere except for
the the IRF510 in the PA.
3. Works without a slow motion drive! Uses two knob tuning for coarse
and fine tuning.
4. Uses fewer different values of resistors and capacitors.
5. Stable design.

73s.

> Has anybody here attempted to use a pic to control a dds chip (and
> wrote the software himself)?
> (snip...)

Or "herself", as the case may be...sheesh.

My very first attempt in this area was a long time
ago. I built a DDS around a Qualcomm parallel-input
DDS chip but got tired of binary computatin and
soldering diodes into a programming board. So I made
a controller with a shaft encoder, a Basic Stamp
and a serial-to-parallel interface cobbled together
out of 74HC logic. It worked fine.

Don't try to do everything at once. Get basic
functionality first, *then* get fancy. Do you
really need umpteen memories, variable tuning rates,
and so on? Right away? Probably not...

My Q2220 controller manipulated the 24 bit tuning
word directly (the steps were 50 million / 2^24,
about 3 Hz), then the software turned this into a
frequency readout. With modern chips you probably
don't want to do it this way around.

It's not a crime to recycle other peoples' code,
like the mundane and generally boring bit-pushing to
talk to a 44780 LCD controller.

I need this service too!

Not sure where you're located, I'm in Toronto, but Durham radio maybe a place to start. I bought my scanner from them. Nice people as I recall. Also, Lakeshore Electronics can probably fix anything - but they're specialty is high-end Motorolas for business and professionals. Give them a call and get a quote.

Good luck - please let us know if you find anywhere near TO. I got a sick Moto that needs some TX tuning.

<< The "impedance" of free space/ air is 377 ohms. Thus the ratio of RF field voltage and current will be
fixed and related to the power density - unless the field is distorted.

As another crude approximation, assume that (unless you know a radiation pattern) that the unwanted signal's power is equally distributed over a sphere or maybe a hemisphere. >>

R. J. & Ed-

The calculations R. J. refers to apply to a field at a distance - called "far field". Up close, radiation patterns are complex and not easily predicted.

For the sake of discussion, lets carry this free space impedance topic a bit further. If you know transmitted power and the type of antenna, you can approximate the effective radiated power. For example, a half wave dipole and a quarter wave ground plane have about the same gain, 2.1 dB. If you are concerned about worst-case, you should assume a handheld radio with a rubber-duckie antenna, has the same gain as a full size ground plane. (You could also add some gain due to reflecting surfaces, just to be safe.)

Suppose your handheld radio has five watts output. For a gain of 2.1 dB, the effective isotropic radiated power is about 8 watts. This power illuminates the inner surface area of a sphere equal to (4/3) Pi R-squared, where R is the distance.

At some distance the field strength will equal an amount that will interfere with the defibrillator. Suppose that critical field strength is one Volt per Meter. One Volt squared, divided by 377 equals 2.7 milliWatts per square Meter.

Working this backwards with the sphere, 4/3 Pi R-squared divided by 8 watts equals the power (2.7 mW) per square meter at distance R. You can calculate that the minimum distance R equals 0.072 Meters, which is less than 3 inches. (Please don't hold any errors against me. Check it yourself!)

Since this distance is well within the near-field region, there is an uncertainty that depends on whether there is electric coupling or magnetic coupling. To be absolutely sure there is no interference, you could back off a couple of wavelengths, say fifteen feet on two meters. (Others may say ten times 3 inches would be enough.)

How does this one Volt per Meter assumption compare with the defibrillator specifications? If the spec is higher, then there seems little to worry about.

Going to make it one of those long days? :-)

OK, so where is the VCO control voltage coming from and how does
it "know" how to reach the right voltage for the right frequency?

It doesn't...because the PFD output (MC4044 type) does not have
to. There will ALWAYS be a small error in any control loop...
otherwise a control loop couldn't function to do controlling (basic
control loop theory which so many seem to forget).

A "charge pump" is basically a voltage-to-current converter to
develop a basically-DC control voltage for the VCO of the PLL
after the loop filtering. One doesn't need to use the charge
pump in the MC4044 or the 11C44 chip. The digital output of
the PFD can go direct to the loop filter. Even with the charge
pump in-use, the whole thing (pump and loop filter or integrator/
filter) simply integrates a time variation (width of repetitious
pulses out of PFD) into a stable DC value.

>In a practical PFD implementation, it is impossible to
>maintain the zero pulse-width point because the PFD is a digital feedback
>circuit, and you would need parts with zero propagation delay to make such a

>circuit.

Absolutely not. There must be SOME gate delay. If there were zero, then every single D or J-K flip-flop would not work! Since they do work, there is always SOME internal gate delay.

That internal IC capacitance causing the delay is the cause for all that heat-dissipation effort on hundred-thousand-plus transistor junction ICs used in single-chip microcomputers. In a 9- or 10-gate IC there isn't a lot of heat rise...but the parasitic gate structure capacitance is always there and all gates have finitie propagation delays.

Some number of years ago I went into the old databooks (so far back they were free for anyone and still had the equivalent circuits in them...like thirty plus years ago) and started doing timing diagrams to see EXACTLY how they worked. Most interesting bit of "reverse engineering" and also quite interesting.

The '44-type PFD digital part is essentially a very complex D FF like structure and it triggers only one direction of transition edges (like the Ds and J-Ks). The '44 is more complex in trying to see how it works due to the various conditions of relative input phases. If there are more than two signal edges for every reference edge, the outputs hold at one state indicating a "way-off" towards the high frequency range end of the signal. If there are more than two reference edges for every signal edge, the outputs flip to the other state...the "way-off" signal frequency is too low.

However, when there is one input edge for each other input edge, the outputs produce a variable-width pulse, repetition rate equal to the reference frequency, which corresponds to the relative phase of the two inputs. The outputs are always "flipping" when the inputs are at the same frequency even though the inputs need NOT be in exact phase positioning. Not a problem. That variable width turns out to be extremely good for control since a simple integrator can convert the variable time into a variable voltage whose DC value is proportional to the relative inputs phase displacement.

An op-amp integrator circuit functions as a sort of time-to-current-to-output-voltage converter (technically, the input R is creating a pseudo-constant-current source for the mid-point of R and C of the integrator op-amp input). That can also be used as a "Type 1" loop filter. With some modifications of a basic integrator, it can become any of the other types. Or, one can, with a sensitive control voltage characteristic of the VCO, use a passive loop filter with the filter input directly on the PFD output (choose either one to go with polarity of the VCO control needed). For that alternate condition, the PFD Vcc *MUST* be stable and decoupled less it mess around with more badness in the control voltage. The "charge pump" circuit of the MC4044/11C44 is really optional

to use. It isn't absolutely necessary although it can cut down on
the number of parts used.

Based on hands-on observation of several of these PLLs, especially
those of PFDs made from individual logic gates, the PFD outputs
ARE pulses at the reference frequency repetition rate. Their width
is proportional to the integrated-averaged DC control voltage of the
VCO when in lock.

If what you say is true, then there would be ZERO control voltage
out of any of the mentioned interface circuits. Obviously, there
must be some finite amount of control voltage for the VCO to
adjust to a particular PLL frequency increment. That control
voltage is the integrated-averaged DC out of the loop filter, not
some mythical "charged whatsis" from that charge pump.

In looking at the relative phases of the signal and reference AC
inputs, the loop is LOCKED even though the phases are
offset. The phases remain "in step" and unchanging on the
'scope but they are offset in phase from one another. [that's
normal with this kind of PFD and PLL] I've been looking at
these things for about three decades and see the same things.
With the MC145151 combo PLL chip I'm playing with now, the
PFD gates aren't fully available for peeking, but it locks in as
advertised as I said above.

>However, the width of the pulses in modern designs can get down
>into the nanosecond range at lock.

Nobody, not even the PLL really cares. How much voltage are
you going to generate on the VCO control line from nanosecond
pulse widths at a 1 KHz reference input repetition rate? Very
little.

>For this reason, the PFD can produce much
>lower sideband content than the XOR, which outputs large pulses at lock. The
>larger the output pulse, the more difficult the loop filter design.

The only thing "difficult" about a PLL is others paying attention to
the REQUIRED values of control voltage gain and the reference
frequency AND the simple math needed to calculate those values.
"Difficult" is when the control voltage isn't linear over frequency
(which upsets the heck out of the control gain at one end of the
VCO range). "Difficult" is not paying attention to the subcircuit
isolation and shielding and decoupling that produces the control
voltage where it is ripe for picking up garbage that results in all
kinds of badness in VCO stability.

> > No. In the '44-type PFD, the output pulses will be zero ONLY if
>> the divided VCO is way off frequency, at one end of the controllable
>> range or the other. IN LOCK the PFD output will ALWAYS HAVE
>> A FINITE PULSE WIDTH at the reference frequency repetition rate.
>> Without that pulse width averaged out there would be NO control

>> voltage to hold the divided VCO within range.
>
>Wrong again! With large frequency errors, the PFD produces constant pumping.
>If it didn't, it couldn't acquire with phase errors larger than 180deg.

No. If you examine the states of all gates in a '44 PFD with
corresponding input waveform states, you will see that the
"way-off" (phase errors larger than 180 degrees) conditions of
the PFD outputs REMAIN in their fully-on or fully-off states.
That's the gem of this gate arrangement and the key to coming
into lock on power-up.

One reason I submitted my article to Jim Fisk at Ham Radio
magazine (it was not in the original sequence at the start of that
series) was as a result of trying to explain the gate-states of the
'44 PFD to another. The waveform timing diagrams in that
September 1982 article accurately show the state changes
(without the precise amount of internal gate delay, not really
needed in explanation). Just to make certain, I'd duplicated the
gate logic in an Apple][program to make sure...and to see the
variations in original conditions that might cause a bad start-up.
I didn't use the conventional bubble-and-arrow state change
diagrams since so few contemporaries could "read" them and
I didn't much care for that kind of presentation either. Waveforms
were an old familiar thing and I stuck with that.

>You are also wrong in asserting that the lock-in range of the PFD is +/- 180
>degrees. In fact, it is infinite (in theory).

"Infinite" only in the grossest sense of being - in effect - locked
up on either of the "way-off" conditions. From what I gather, it
was designed to do that very thing. An excellent thing to insure
start-up.

However, integrated-averaged to DC, the outputs of the PFD make
an excellent phase meter with a DC that can be converted to
binary in an A-to-D. The Rocketdyne Deformable Mirror project
used that characteristic to measure the heterodyned optical
signals from the optics at 1 MHz PFD input. It worked just fine
out to about +/- 179 degrees or so when calibrated for the whole
optical-electronic loop. [optics could approach 180 but never
quite get exactly there...but then that's difficult with electronics
also, needing time-interval averaging counters and such which
we DID use...but the optics folks wanted to tweak their stable
table optics more than tweaking instrument dials...:-)]

>Yes, its linear output
>compliance range is +/- 180 degrees, but it can acquire lock even when there
>is an infinite frequency error. This is because once the PFD output exceeds
>it's compliance range, it outputs a constant "pump up" or "pump down" pulse
>train, which in turn causes the loop filter voltage to ramp up or down as
>the case might be until the signal comes back into the compliance range and

>lock is established.

No. At beyond-control-range input frequencies, the PFD outputs
go to their stable, unchanging "way-off" states and stay there
until both inputs are the same frequency. Ain't no "pump" pulses
whatsoever at those "way-off" conditions.

>The XOR's big advantage is that it is simple, and there is no discontinuity
>around the phase lock point (as there is in the PFD), but it does not lock
>up readily in the face of frequency errors. The PFD's advantage is that it
>readily locks up, even in the face of large frequency errors and it also
>produces an easily filtered output.

In practice, since the last days of WW2, phase-frequency control
loops have used lots of extra circuitry to cure that start-up. Philco
did that with some S-band microwave radio relay gear used by the
USAF in 1955. Army used L-band crystal-controlled microwave
radio relay terminals by GE, had no problems. USAF had Philco
tech reps there seemingly all the time since their frequency control
tended to pop off lock and go sweeping frequency a lot from their
extra sawtooth circuitry. [PLL was first disclosed in 1932 by
"H. de Bellecize, working in France" according to my giant
1980 50th anniversary special edition of Electronics magazine]

There have been a few PFD circuits devised before the '44 type
but I'd say the '44 went all the way to excellence with elegance
in its simplicity. There have been at least one close to the '44
but arranged differently and with more internal parts...but that one
works about the same as the '44.

When you get the chance, grab a 'scope and look into the
waveforms of a PFD as well as the control voltage. You will
find out I'm right. No "theory" on that, just working PLL
hardware. I've seen and observed that, used the basic
knowledge to build my own PLLs (including a couple just for
me) and am confident in the explanation I gave. They WORK
by all the nice instruments from Hewlett and Packard (rest
their souls).

Hi,

I have wanted to get involved with shortwave for years and would like to get some recommendations on a mid-range ($200-400) receiver and antenna set-up. I plan on telescoping mast for shortwave, TV (mostly for uhf PBS stuff), and FM. The height restriction in our town is 50' but I imagine anything around 30' would produce good results since there are no big hills or trees nearby. In addition I own a newer 2.8 GHz PC running Windows XP for any recommendations on how I might incorporate this into the overall set-up.

Being inexperienced I am thinking I should start with simply listening with a capable mid-range receiver and then after some years time buy into a transmitter as well. This is all untutored preliminary thinking on my part and would welcome anyone's ideas as to how a beginner could best get started on the road to mid-to-high end shortwave/ham listening/broadcasting. I see this initial step as phase one of a two or three part program that will extend over a period of five or ten years.

Thank you for your help.

Steve

Note: I will be buying "Passport to World Band Radio" as a way of educating myself on some of the issues I mentioned

> 73, Leon
>

Thanks, Leon and Pete. This oldest of the 13.56 MHz power units has no fasteners visible on the top surface, so I figure it has to be fastened from the inside. I tried to look up through the bottom, but too many components were in the way. It usually shows up on Ebay at a pretty low price, presently there's one at $14.99 with no bid. I kinda like them because there are no funky RF switches to go bad. Some of the RFG-30 units have LED indicators, but out of 4 units, 3 of mine have incandescent lamps behind the front Metcal logo that no longer light up. Yes, that would really be a buzz, "rig here is a 30 watt Metcal RF Generator"! ! ! Might not be too hard to do.

These things must be exceptionally reliable since there's almost no information available (or needed, apparently) on how to repair them - - they must not be failing.

73, Chuck

I have one and it's performs nearly equal to the Sony ICF 2010 /2001D.
Not too bad for a a widerange communications receiver.
For shortwave only I would take a look on the RX320 from TenTec when
going on a computer controled blackbox...
It is also DRM ready. Have a look:
http://www.universal-radio.com/catalog/commrxvr/0321.html

I've bookmarked your page and the one you linked to for futher
reference. I'm in the process of designing and building a rig myself.
The final parameters are in flux at the momement. I recently bagged
a lot of 414 8.3688 mhz crystals on ebay (at less than 5 cents a rock)
in HC6U cases. I need to build a sweep oscillator to build a filter
around these cystals. However since my rig will be using an AD9954 DDS
vfo (which HAS sweep ability built in with a ram lookup table) I think
I will be building the vfo / microprocessor section first! I have a
number of PIC chips on order and I am getting the development tools
installed on my Linux box. I'm also in the process of building a PIC
programmer. (Amazing how one project spawns many others!).

I'll probably use a pair of IRF510's in push pull for my final. I've
heard they can produce as much as 40-50w out, but I'll be happy to get
25w. I've been stocking up on -2 and -6 toroids whenever I found a
batch on ebay. I had this crazy idea of building a switchable bpf
into an old TV turret tuner with removable coil strips. The band
switch would be the old tuner, I could add a 12 position rotary switch
to the back and have the micro processor read the switch.

Here's the DRM schedule:

http://drm.org/livebroadcast/globfieldtrial.htm

The transmissions from Sackville are a good bet. On an analog radio, it
sounds like a whole SW channel of constant hissing .

Frank Dresser
